EMPLOYMENT, HOURS, AND EARNINGS DATA FROM ESTABLISHMENT SURVEYS

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by 162,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

LABOR TURNOVER DATA in this section are compiled from personnel records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies. A sample of 40,000 establishments represents all industries in the manufacturing and mining sectors of the economy.

Definitions

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 14–20 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in transportation and public utilities, in wholesale and retail trade, in finance, insurance, and real estate, and in service industries. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to eliminate the effects of price change. The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries. **Spendable earnings** are earnings from which estimated social security and Federal income taxes have been deducted. The Bureau of Labor Statistics computes spendable earnings from gross weekly earnings for only two illustrative cases: (1) a worker with no dependents and (2) a married worker with three dependents.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

Labor turnover is the movement of all wage and salary workers from one employment status to another. **Accession rates** indicate the average number of persons added to a payroll in a given period per 100 employees; **separation rates** indicate the average number dropped from a payroll per 100 employees. Although month-to-month changes in employment can be calculated from the labor turnover data, the results are not comparable with employment data from the employment and payroll survey. The labor turnover survey measures changes during the calendar month while the employment and payroll survey measures changes from midmonth to midmonth.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of September 1979 data, published in the November 1979 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Complete comparable historical unadjusted and seasonally adjusted data are published in a Supplement to Employment and Earnings (unadjusted data from April 1977 through June 1979 and seasonally adjusted data from January 1974 through June 1979) and in *Employment and Earnings, United States, 1909–78*, BLS Bulletin 1312–11 (for prior periods).

Data on recalls were shown for the first time in tables 12 and 13 in the January 1978 issue of the *Review*. For a detailed discussion of the recalls series, along with historical data, see "New Series on Recalls from the Labor Turnover Survey," *Employment and Earnings*, December 1977, pp. 10–19.

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20. See also *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976).

The formulas used to construct the spendable average weekly earnings series reflect the latest provisions of the Federal income tax and social security tax laws. For the spendable average weekly earnings formulas for the years 1978–80, see *Employment and Earnings*, March 1980, pp. 10–11. Real earnings data are adjusted using the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

NOTE: The earnings expressed in 1967 dollars have been adjusted for changes in price level as measured by the Bureau's Consumer Price Index for Urban Wage Earners and Clerical Workers.

These series are described in "The Spendable Earnings Series: A Technical Note on its Calculation", **Employment and Earnings and Monthly Report on the Labor Force,** February 1969, pp. 6-13. See also "Spendable Earnings Formulas, 1978-80" **Employment and Earnings,** March 1980, pp. 10-11.

UNEMPLOYMENT INSURANCE DATA

UNEMPLOYMENT INSURANCE DATA are compiled monthly by the Employment and Training Administration of the U.S. Department of Labor from records of State and Federal unemployment insurance claims filed and benefits paid. Railroad unemployment insurance data are prepared by the U.S. Railroad Retirement Board.

Definitions

Data for **all programs** represent an unduplicated count of insured unemployment under the State, Ex-Servicemen, and UCFE programs, and the Railroad Insurance Act.

Under both State and Federal unemployment insurance programs for civilian employees, insured workers must report the completion of at least 1 week of unemployment before they are defined as unemployed. Persons not covered by unemployment insurance (about one-third of the labor force) and those who have exhausted or not yet earned benefit rights are excluded from the scope of the survey. **Initial claims** are notices filed by persons in unemployment insurance programs to indicate they are out of work and wish to begin receiving compensation. A claimant who continued to be unemployed a full week is then counted in the insured unemployment figure. The **rate of insured unemployment** expresses the number of insured unemployed as a percent of the average insured employment in a 12-month period.

An **application** for benefits is filed by a railroad worker at the beginning of his first period of unemployment in a benefit year; no application is required for subsequent periods in the same year. **Number of payments** are payments made in 14-day registration periods. The **average amount of benefit payment** is an average for all compensable periods, not adjusted for recovery of overpayments or settlement of underpayments. However, **total benefits** paid have been adjusted.

21. Unemployment insurance and employment service operations

[All items except average benefits amounts are in thousands]

Item	1979												1980
	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.

[1] Initial claims and State insured unemployment include data under the program for Puerto Rican sugarcane workers.

[2] Includes interstate claims for the Virgin Islands. Excludes transition claims under State programs.

[3] Excludes data on claims and payments made jointly with other programs.

[4] Includes the Virgin Islands. Excludes data on claims and payments made jointly with State programs.

[5] Cumulative total for fiscal year (October 1 - September 30).

NOTE: Data for Puerto Rico included. Dashes indicate data not available.

PRICE DATA

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Definitions

The **Consumer Price Index** is a monthly statistical measure of the average change in prices in a fixed market basket of goods and services. Effective with the January 1978 index, the Bureau of Labor Statistics began publishing CPI's for two groups of the population. One index, a new CPI for All Urban Consumers, covers 80 percent of the total noninstitutional population; and the other index, a revised CPI for Urban Wage Earners and Clerical Workers, covers about half the new index population. The All Urban Consumers index includes, in addition to wage earners and clerical workers, professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctor's and dentist's fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items is kept essentially unchanged between major revisions so that only price changes will be measured. Prices are collected from over 18,000 tenants, 24,000 retail establishments, and 18,000 housing units for property taxes in 85 urban areas across the country. All taxes directly associated with the purchase and use of items are included in the index. Because the CPI's are based on the expenditures of two population groups in 1972–73, they may not accurately reflect the experience of individual families and single persons with different buying habits.

Though the CPI is often called the "Cost-of-Living Index," it measures only price change, which is just one of several important factors affecting living costs. Area indexes do not measure differences in the level of prices among cities. They only measure the average change in prices for each area since the base period.

Producer Price Indexes measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes contains about 2,800 commodities and about 10,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The universe includes all commodities produced or imported for sale in commercial transactions in primary markets in the United States.

Producer Price Indexes can be organized by stage of processing or by commodity. The stage of processing structure organizes products by degree of fabrication (that is, finished goods, intermediate or semifinished goods, and crude materials). The commodity structure organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States, from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

In calculating Producer Price Indexes, price changes for the various commodities are averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage of processing groupings, commodity groupings, durability of product groupings, and a number of special composite groupings.

Price indexes for the output of selected SIC industries measure average price changes in commodities produced by particular industries, as defined in the *Standard Industrial Classification Manual 1972* (Washington, U.S. Office of Management and Budget, 1972). These indexes are derived from several price series, combined to match the economic activity of the specified industry and weighted by the value of shipments in the industry. They use data from comprehensive industrial censuses conducted by the U.S. Bureau of the Census and the U.S. Department of Agriculture.

Notes on the data

Beginning with the May 1978 issue of the *Review*, regional CPI's cross classified by population size, were introduced. These indexes will enable users in local areas for which an index is not published to get a better approximation of the CPI for their area by using the appropriate population size class measure for their region. The cross-classified indexes will be published bimonthly. (See table 24.)

For further details about the new and the revised indexes and a comparison of various aspects of these indexes with the old unrevised CPI, see *Facts About the Revised Consumer Price Index*, a pamphlet in the Consumer Price Index Revision 1978 series. See also *The Consumer Price Index: Concepts and Content Over the Years*. Report 517, revised edition (Bureau of Labor Statistics, May 1978).

For interarea comparisons of living costs at three hypothetical standards of living, see the family budget data published in the *Handbook of Labor Statistics, 1977*, Bulletin 1966 (Bureau of Labor Statistics, 1977), tables 122–133. Additional data and analysis on price changes are provided in the *CPI Detailed Report* and *Producer Prices and Price Indexes*, both monthly publications of the Bureau.

As of January 1976, the Wholesale Price Index (as it was then called) incorporated a revised weighting structure reflecting 1972 values of shipments. From January 1967 through December 1975, 1963 values of shipments were used as weights.

For a discussion of the general method of computing consumer, producer, and industry price indexes, see *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), chapters 13–15. See also John F. Early, "Improving the measurement of producer price change," *Monthly Labor Review*, April 1978, pp. 7–15. For industry prices, see also Bennett R. Moss, "Industry and Sector Price Indexes," *Monthly Labor Review*, August 1965, pp. 974–82.

---

[1] Prices for natural gas are lagged 1 month.

[2] Includes only domestic production.

[3] Most prices for refined petroleum products are lagged 1 month.

[4] Some prices for industrial chemicals are lagged 1 month.

[5] Not available.

NOTE: Data for October 1979 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

28. Producer Price Indexes, for special commodity groupings

[1967 = 100 unless otherwise specified]

Commodity grouping	Annual average 1978	1979 Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	1980 Jan.	Feb.
All commodities — less farm products	206.4	222.0	224.7	228.0	230.1	232.0	235.4	237.5	241.4	245.3	246.7	249.2	219.3	260.5
All foods	206.4	225.0	225.9	227.7	226.4	223.8	225.4	224.7	228.5	226.9	229.9	232.1	219.9	235.7
Processed foods	206.7	223.5	225.6	227.8	227.5	224.7	226.4	224.8	230.8	228.9	231.8	234.1	219.8	238.5
Industrial commodities less fuels	197.2	209.6	211.9	214.7	216.0	217.0	219.0	220.3	222.0	225.9	226.4	228.1	207.3	237.5
Selected textile mill products (Dec. 1975 = 100)	108.8	110.8	111.6	112.3	112.8	113.5	114.0	115.1	115.8	116.4	116.1	117.0	109.8	119.4
Hosiery	106.3	109.9	110.5	112.5	112.5	112.7	114.1	113.0	112.7	113.3	114.6	115.3	110.1	119.6
Underwear and nightwear	158.9	166.3	167.1	167.3	167.7	168.3	168.5	170.8	170.8	171.2	171.6	172.9	164.6	177.8
Chemicals and allied products, including synthetic rubber and manmade fibers and yarns	190.5	198.0	200.0	204.1	207.6	209.5	215.0	218.6	220.9	224.3	226.0	228.6	196.3	238.2
Pharmaceutical preparations	140.6	149.0	149.4	150.0	150.1	151.7	151.7	152.0	153.6	155.6	155.4	156.9	148.1	160.4
Lumber and wood products, excluding millwork and other wood products	298.3	317.0	323.7	326.4	325.1	321.7	325.3	333.9	341.0	337.3	323.5	310.3	314.8	314.0
Special metals and metal products	209.6	225.6	228.2	232.7	232.4	233.7	235.5	234.9	236.4	243.4	244.2	245.9	222.0	255.7
Fabricated metal products	216.2	228.6	230.6	232.9	234.6	235.7	237.4	239.8	241.1	244.0	244.8	245.6	227.0	248.3
Copper and copper products	155.6	188.2	197.9	212.1	199.0	193.0	191.9	197.1	200.5	212.2	213.6	216.1	168.8	258.2

NOTE: Data for October 1979 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

PRODUCTIVITY DATA

PRODUCTIVITY DATA are compiled by the Bureau of Labor Statistics from establishment data and from estimates of compensation and output supplied by the U.S. Department of Commerce and the Federal Reserve Board.

Definitions

Output is the constant dollar gross domestic product produced in a given period. Indexes of **output per hour of labor input,** or labor productivity, measure the value of goods and services produced per hour of labor. **Compensation per hour** includes wages and salaries of employees plus employers' contributions for social insurance and private benefit plans. The data also include an estimate of wages, salaries, and supplementary payments for the self-employed, except for nonfinancial corporations, in which there are no self-employed. **Real compensation per hour** is compensation per hour adjusted by the Consumer Price Index for All Urban Consumers.

Unit labor cost measures the labor compensation cost required to produce one unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from the current dollar gross domestic product and dividing by output. In these tables, **Unit nonlabor costs** contain all the components of unit nonlabor payments except unit profits. **Unit profits** include corporate profits and inventory valuation adjustments per unit of output.

The **implicit price deflator** is derived by dividing the current dollar estimate of gross product by the constant dollar estimate, making the deflator, in effect, a price index for gross product of the sector reported.

The use of the term "man-hours" to identify the labor component of productivity and costs, in tables 31 through 34, has been discontinued. **Hours of all persons** is now used to describe the labor input of payroll workers, self-employed persons, and unpaid family workers. **Output per all-employee hour** is now used to describe labor productivity in nonfinancial corporations where there are no self-employed.

Notes on the data

In the private business sector and the nonfarm business sector, the basis for the output measure employed in the computation of output per hour is Gross Domestic Product rather than Gross National Product. Computation of hours includes estimates of nonfarm and farm proprietor hours.

Output data are supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are from the Bureau of Economic Analysis and the Bureau of Labor Statistics.

Beginning with the September 1976 issue of the *Review,* tables 31–34 were revised to reflect changeover to the new series—private business sector and nonfarm business sector—which differ from the previously published total private economy and nonfarm sector in that output imputed for owner-occupied dwellings and the household and institutions sectors, as well as the statistical discrepancy, are omitted. For a detailed explanation, see J. R. Norsworthy and L. J. Fulco, "New sector definitions for productivity series," *Monthly Labor Review,* October 1976, pages 40–42.

LABOR-MANAGEMENT DATA

MAJOR COLLECTIVE BARGAINING DATA are obtained from contracts on file at the Bureau of Labor Statistics, direct contact with the parties, and from secondary sources. Additional detail is published in *Current Wage Developments,* a monthly periodical of the Bureau. Data on work stoppages are based on confidential responses to questionnaires mailed by the Bureau of Labor Statistics to parties involved in work stoppages. Stoppages initially come to the attention of the Bureau from reports of Federal and State mediation agencies, newspapers, and union and industry publications.

Definitions

Data on wage changes apply to private nonfarm industry agreements covering 1,000 workers or more. Data on wage and benefit changes *combined* apply only to those agreements covering 5,000 workers or more. **First-year wage settlements** refer to pay changes going into effect within the first 12 months after the effective date of the agreement. **Changes over the life of the agreement** refer to total agreed upon settlements (exclusive of potential cost-of-living escalator adjustments) expressed at an average annual rate. **Wage-rate changes** are expressed as a percent of straight-time hourly earnings, while **wage and benefit changes** are expressed as a percent of total compensation.

Effective wage-rate adjustments going into effect in major bargaining units measure changes actually placed into effect during the reference period, whether the result of a newly negotiated increase, a deferred increase negotiated in an earlier year, or as a result of a cost-of-living escalator adjustment. Average adjustments are affected by workers receiving no adjustment, as well as by those receiving increases or decreases.

Work stoppages include all known strikes or lockouts involving six workers or more and lasting a full shift or longer. Data cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

35. Wage and benefit settlements in major collective bargaining units, 1975 to date
[In percent]

Sector and measure	Annual average					Quarterly average						
	1975	1976	1977	1978	1979 [p]	1978			1979 [p]

How to order BLS publications

PERIODICALS

Order from (and make checks payable to) Superintendent of Documents, Washington, D.C. 20402. For foreign subscriptions, add 25 percent.

Monthly Labor Review. The oldest and most authoritative government research journal in economics and the social sciences. Current statistics, analysis, developments in industrial relations, court decisions, book reviews. $18 a year, single copy, $2.50.

Employment and Earnings. A comprehensive monthly report on employment, hours, earnings, and labor turnover by industry, area, occupation, et cetera $22 a year, single copy $2.75.

Occupational Outlook Quarterly. A popular periodical designed to help high school students and guidance counselors assess career opportunities. $6 for four issues, single copy $1.75.

Current Wage Developments. A monthly report about collective bargaining settlements and unilateral management decisions about wages and benefits; statistical summaries. $12 a year, single copy $1.35.

Producer Prices and Price Indexes. A comprehensive monthly report on price movements of both farm and industrial commodities, by industry and stage of processing. $17 a year, single copy $2.25.

CPI Detailed Report. A monthly periodical featuring detailed data and charts on the Consumer Price Index. $15 a year, single copy $2.25.

PRESS RELEASES

The Bureau's statistical series are made available to news media through press releases issued in Washington. Many of the releases also are available to the public upon request. Write: Bureau of Labor Statistics, Washington, D.C. 20212.

Regional. Each of the Bureau's eight regional offices publishes reports and press releases dealing with regional data. Single copies available free from the issuing regional office.

BULLETINS AND HANDBOOKS

About 140 bulletins and handbooks published each year are for sale by regional offices of the Bureau of Labor Statistics (see inside front cover) and by the Superintendent of Documents. Washington, D.C. 20402. Make checks payable to the Superintendent of Documents. Among the bulletins and handbooks currently in print are these:

Occupational Outlook Handbook, 1978–79 Edition. Bulletin 1955. A useful resource supplying valuable assistance to all persons seeking satisfying and productive employment. $8, paperback; $11 hard cover.

BLS Handbook of Labor Statistics 1978. Bulletin 2000. A 604-page volume of historical data on the major BLS statistical series. $9.50.

Handbook of Methods. Bulletin 1910. Brief technical account of each major statistical program of the Bureau of Labor Statistics. $3.50.

BLS Measures of Compensation. Bulletin 1941. An introduction to the various measures of employee compensation; describes each series, the manner in which it is developed, its uses and limitations. $2.75.

Occupational Projections and Training Data. Bulletin 2020. Presents both general and detailed information on the relationship between occupational requirements and training needs. (Updates Bulletin 1918 published in 1976.) $3.25.

Technological Change and its Labor Impact in Five Energy Industries. Bulletin 2005. A 64-page study appraising major technological change and discussing the impact of these changes on productivity and occupations over the next 5 to 10 years. $2.40.

BLS Publications, 1972–77. Bulletin 1990. A numerical listing and subject index of bulletins and reports issued by the Bureau from 1972 through 1977, supplementing Bulletin 1749, covering 1886–1971. $1.80.

International Comparisons of Unemployment. Bulletin 1979. Brings together all of the Bureau's work on international unemployment comparisons. Describes the methods of adjusting foreign unemployment rates in 8 countries to U.S. concepts. $3.50.

Productivity Indexes for Selected Industries, 1979 Edition. Bulletin 2054. A 190-page report of indexes of output, employment, and employee hours in selected industries from 1954 to 1978. This edition contains measures for three industries previously not covered, as well as components of previously published measures in 10 industries. $5.50.

Profiles of Occupational Pay: A Chartbook. Bulletin 2037. A graphic illustration of some of the factors that affect workers' earnings. This three-part presentation looks at wage variations among and within occupations and portrays characteristics of high- and low-paying urban areas and manufacturing industries. $3.50.

REPORTS AND PAMPHLETS

Single copies available free from the BLS regional offices or from the Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

How the Government Measures Unemployment. Report 505. A concise report providing a background for appraising developments in the area of unemployment.

Directory of BLS Studies in Industrial Relations 1960–78. Report 550. A listing of studies prepared by the Division of Industrial Relations as part of the Bureau's regular program of data collection and analysis in the field of industrial relations.

☆U.S. GOVERNMENT PRINTING OFFICE: 1980 O— 311-406/32

Directory of National Unions and Employee Associations, 1977

Bulletin 2044

This Bureau of Labor Statistics directory lists names and addresses of:

- National and international unions
- State labor organizations
- Professional and public employee associations, their officers and key officials, publications, information about their conventions, membership, and number of locals.

Factbook section of the publication includes a report on developments in the labor movement, 1976-77, and facts about the structure of the labor movement. Information about the level, trend, and composition of membership is supplied by the participating organizations. Extensive statistical appendixes are included.

Labor Month In Review

KLEIN AWARD. The trustees of the Lawrence R. Klein Fund selected a single article to receive the 11th annual Klein Award. The article, "The effect of demographic changes on the Nation's unemployment rate," appeared in the March 1979 *Monthly Labor Review*. Its author, Paul O. Flaim, is chief of the Division of Labor Force Studies in the BLS Office of Current Employment Analysis.

Runners-up among articles by BLS authors were "Young and marginal: an overview of youth employment," by Norman Bowers, October 1979, and "The influence of energy on industry output and employment," by Ronald E. Kutscher, December 1979.

The trustees presented no award this year to an author outside BLS. Nevertheless, the trustees expressed admiration for Thomas A. Kochan's "How American workers view labor unions," April 1979, Graham L. Staines' and Robert P. Quinn's "American workers evaluate the quality of their jobs," January 1979, and Joseph H. Wex's and William S. McGee's "Unionization of court employees has raised legal, practical questions," August 1979. The Kochan and Staines-Quinn articles were based on the Quality of Employment Survey, conducted by the Survey Research Center of the University of Michigan for the U.S. Department of Labor. The trustees also cited several "excellent" articles based on papers commissioned by the National Commission on Employment and Unemployment Statistics.

Flaim's article separates cyclical influences on the unemployment rate from noncyclical factors such as changes in the composition of the labor force. Flaim finds that the large increase in the proportion of the labor force which resulted from the maturing of the post-World War II baby boom was one of the demographic factors which exerted upward pressure on the unemployment rate over the past two decades. Flaim estimates that from 0.6 to 1.0 percentage point of the increase in the overall unemployment rate over the 1957-77 period can be attributed to the changing composition of the labor force. The effect of the demographic factors should dissipate gradually during the 1980's, Flaim concludes.

Origin of the award. For more than half a century, writing for the *Monthly Labor Review* was its own reward. Lawrence R. Klein changed that when he retired as *Review* editor in 1968. Instead of accepting a retirement gift, he matched the money collected for that purpose and established a fund to reward good writing and original research in the *Review*.

Since 1969, fund trustees (including Klein) have presented awards to authors of 19 *Review* articles on the basis of these criteria: originality of ideas or method of analysis, adherence to principles of scientific inquiry, and good writing. Awards, which initially carried cash prizes of $100 each, are now $200.

Contributions to the Lawrence R. Klein Award Fund are tax deductible and may be sent to Ben Burdetsky, Secretary-Treasurer, Lawrence R. Klein Award Fund, c/o School of Government and Business Administration, The George Washington University, Washington, D.C. 20052. □

The winners

Mollie Orshansky, a social insurance research analyst at the Social Security Administration, won the first Lawrence R. Klein Award in 1970 for her article explaining "How poverty is measured" in the February 1969 *Monthly Labor Review*. Eighteen other BLS and outside authors have been honored since. Here is the complete list of winners:

1970	Mollie Orshansky	1976	Curtis Gilroy Nicholas Ashford
1971	Hyman Kaitz		
1972	Janice N. Hedges Denis Johnston	1977	Constance Sorrentino Rita M. Maldonado
1973	Peter Henle T. Aldrich Finegan	1978	William Deuterman Harold Douty
1974	Robert W. Fisher Jonathan Grossman	1979	Morris Newman Fred Best
1975	John Early Joseph Mire	1980	Paul O. Flaim

Double-digit inflation today and in 1973–74: a comparison

Energy, housing, and materials spurred the acceleration of prices in both periods; how inflation slowed dramatically in 1975 points to factors to watch currently

BY JOHN F. EARLY, CRAIG HOWELL
AND ANDREW CLEM

The decade just ended was marked by two distinct periods of double-digit inflation, a combination unprecedented in peacetime. The first price surge occurred in 1973–74, and the second began in 1978 and has continued into 1980.

In this article, we describe the life cycle of the first period and examine the first two stages of the current inflation. We identify factors which generated and sustained inflation rates in the neighborhood of 13 percent and reduced inflation to an average of about half that rate for more than 2 years in the intervening period. This comparison can provide a basis for a better understanding of the current situation.

The two periods have a number of similarities, including:

- Rapid runups in prices for energy, especially petroleum-based fuels, which occurred just as prices for other items were approaching double-digit inflation;
- Early, sharp increases in food prices;
- Steep rises in home prices and mortgage interest rates for at least 2 years after the housing market began to soften;
- Major indirect effects from the increases in energy prices within 3 to 6 months of the crude energy price boosts;
- Rapid commodity inflation among crude and intermediate materials other than food and energy; and
- Significant declines in the value of the dollar in international markets, which further aggravated inflation.

Some of the differences between the two periods include:

- The larger relative increases in the price of oil imported from members of the Organization of Petroleum Exporting Countries during the earlier period;
- The more protracted OPEC increases in the current period;
- The greater role of shortages and worldwide commodity inflation in the earlier period;
- The effect of speculation in the current period;
- The greater inflationary impact of energy costs on retail food prices in the current period;
- The impact of an inflationary-expectations psychology on saving, debt, and prices in the current period; and
- The delay in rapid price rises for natural gas until relatively late in the earlier period.

We also discuss factors contributing to the slowdown in price increases during 1974–75, including:

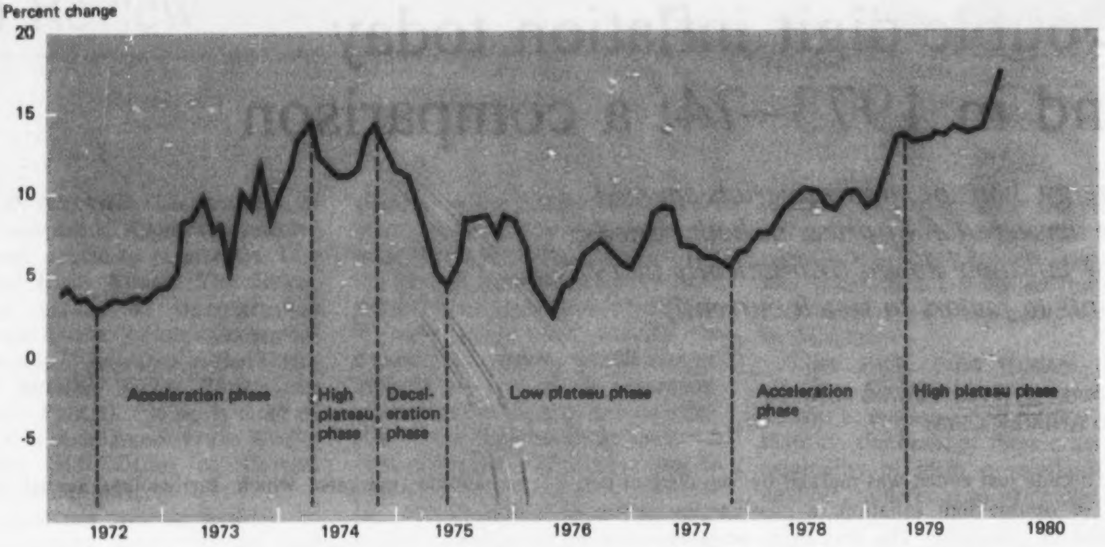
- The precipitous drop in business activity in late 1974;
- The substantial deceleration in prices of crude and intermediate materials; and
- The cessation of major crude petroleum price increases and the completion of most indirect pass-through effects on prices of other goods and services.

As an analytical aid, we have identified four stages in these two periods of inflation. The first is the *low plateau.* From January 1971 until May 1972, the Consumer Price Index increased at an annual rate of about

---

John F. Early is Assistant Commissioner for Industrial Prices and Price Indexes, Bureau of Labor Statistics. Craig Howell and Andrew Clem are economists in the Division of Industrial Prices and Price Indexes. The authors were assisted by William Thomas and James Webbenhurst, economists in the same office.

Chart 1. Inflation rate[1] of the Consumer Price Index for All Urban Consumers, 1972-80



[1] Inflation rate is the 3-month change, seasonally adjusted at annual rates.

3.5 percent. During that time, the seasonally adjusted 3-month annual rate of change generally varied between 2 and 5 percent, partly as the result of the Government's comprehensive wage and price controls, which started in August 1971.[1] A similar low plateau lasted from May 1975 until October 1977. During this time, prices were rising at an average rate of about 6 percent; however, there was somewhat greater volatility around this average, reflecting, in part, wide swings in food prices. But once again the variation was within a relatively narrow range. (See chart 1.)

After both May 1972 and October 1977, prices began to rise at generally increasing rates. This signaled the beginning of the *acceleration* phase. In the earlier case, it lasted 22 months, with price increases accelerating from a 3-month annual rate of 2.6 percent to 14.3 percent; in the later case, it lasted 17 months, as prices accelerated from a 5.1-percent rate to 13 percent.

What can be characterized as *high plateaus* followed the rapid accelerations. From March through October 1974, inflation averaged about 12.5 percent. For the 11 months ended in February 1980, inflation averaged about 14 percent. In both cases there were some changes in the inflation rate during this high plateau phase, but, by definition, a high plateau is not marked by a clear acceleration or deceleration. Because the current period of double-digit inflation has not yet come to an end as of this writing, there is some ambiguity in dating its phases. It is not yet clear whether the 17.2-percent annual rate of advance in the All Items CPI for the 3 months ended in February 1980 represents a short-term fluctuation within the high plateau stage or a resumption of acceleration.

Finally, the CPI began its *deceleration* phase in October 1974. Over the next 7 months, inflation plummeted from a rate of 14.2 percent to 4.4 percent.

A profile of the two periods

1973–74. An upturn in food prices in the spring of 1972 was directly responsible for the acceleration in the All Items CPI, as prices for most other goods were subject to the strict provisions of the Administration's Phase II price control program. (See table 1 and chart 2.) In May 1972, the CPI for food was rising at a 3-month annual rate of only 1.3 percent; but by the following April it was climbing at a 25.4-percent rate. Food price increases slowed considerably in mid-1973 when a 60-day price freeze was imposed, and surged again after the freeze was lifted. Food price increases

[1] Computations are made as though the end of the All Items CPI high plateau phase were February 1980. However, there is yet no evidence of any deceleration.

[2] Energy price increases at the beginning of 1980 may indicate the start of a new acceleration phase.

[3] Phase was not well defined.

[4] No evidence that the acceleration phase has ended for these indexes. For purposes of computation, February 1980 was assumed to be the end of the acceleration phase.

fluctuated widely thereafter, rising a total of 12.2 percent in 1974.

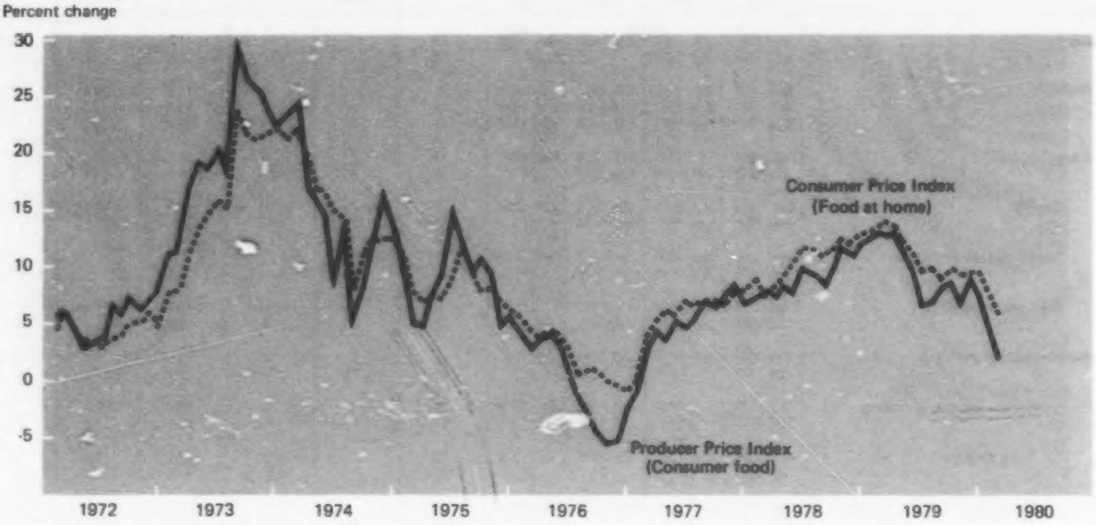
Energy prices boomed at the end of 1973 and the beginning of the next year. (See chart 3.) After rising at a rate of only 2.3 percent in the third quarter of 1973, energy prices soared at a 49.8-percent rate in the fourth quarter and a 66.8-percent rate in the first 3 months of 1974. The index did not remain on a high plateau but immediately began to slow down; by the summer of 1974, energy prices were no longer rising at a double-digit rate.

The CPI for all items other than food and energy started its acceleration phase in the late summer of 1973 after the freeze on prices. Through the rest of 1973 and into the spring of 1974, the Administration gradually dismantled its comprehensive program to control prices and wages. All remaining general price controls lapsed as of April 30, 1974, as Congress did not renew the President's authority to impose such controls. By October 1974, the CPI for nonfood nonenergy items was advancing at an annual rate of 14.2 percent. Some increases reflected the pass-through of sharply higher costs for fuels and energy-intensive materials and thus would have been allowed even under the former controls. Other advances reflected attempts by producers to restore traditional profit margins and to recover costs which could not be fully passed through under the rules of the controls program.

The indexes for food, energy, and other items each contributed roughly one-third of the total acceleration in the All Items CPI from May 1972 through March 1974. (See table 2.) Food prices were the dominant factor until mid-1973, when the acceleration in increases for energy and other items became crucial. The high plateau in the overall inflation rate during much of 1974 reflected a balance between slower rates for energy and steeper rates for items other than food and energy, with food prices climbing briskly throughout the period. The deceleration of the CPI from October 1974 through May 1975 showed the combined impact of food prices, which moved from a 19.3-percent rate of increase to a 1.2-percent rate of decline, and other nonenergy prices, which slowed from a rate of increase of 14.2 percent to 5.9 percent. Energy price increases had already decelerated to a rate of less than 5 percent by the time the CPI started to slow down, but then moved back up to a 3-month rate of 10 percent by May 1975.

1978–79. The acceleration of the All Items CPI after October 1977 followed the trough of the previous recession

Chart 2. Inflation rates for retail and producer prices of food, 1972-80[1]



[1] Twelve-month percent changes in Consumer Price Index for All Urban Consumers (food at home) and the Producer Price Index for consumer food.

by about two and one-half years. As of October 1977, the indexes for food, energy, and other items were all rising at rates between 5 and 6 percent. By the time the CPI had reached a high plateau in March 1979, energy prices were surging at a 25.7-percent rate, food prices were climbing at a 16-percent rate, and prices for other items were increasing at a rate of just over 10 percent.

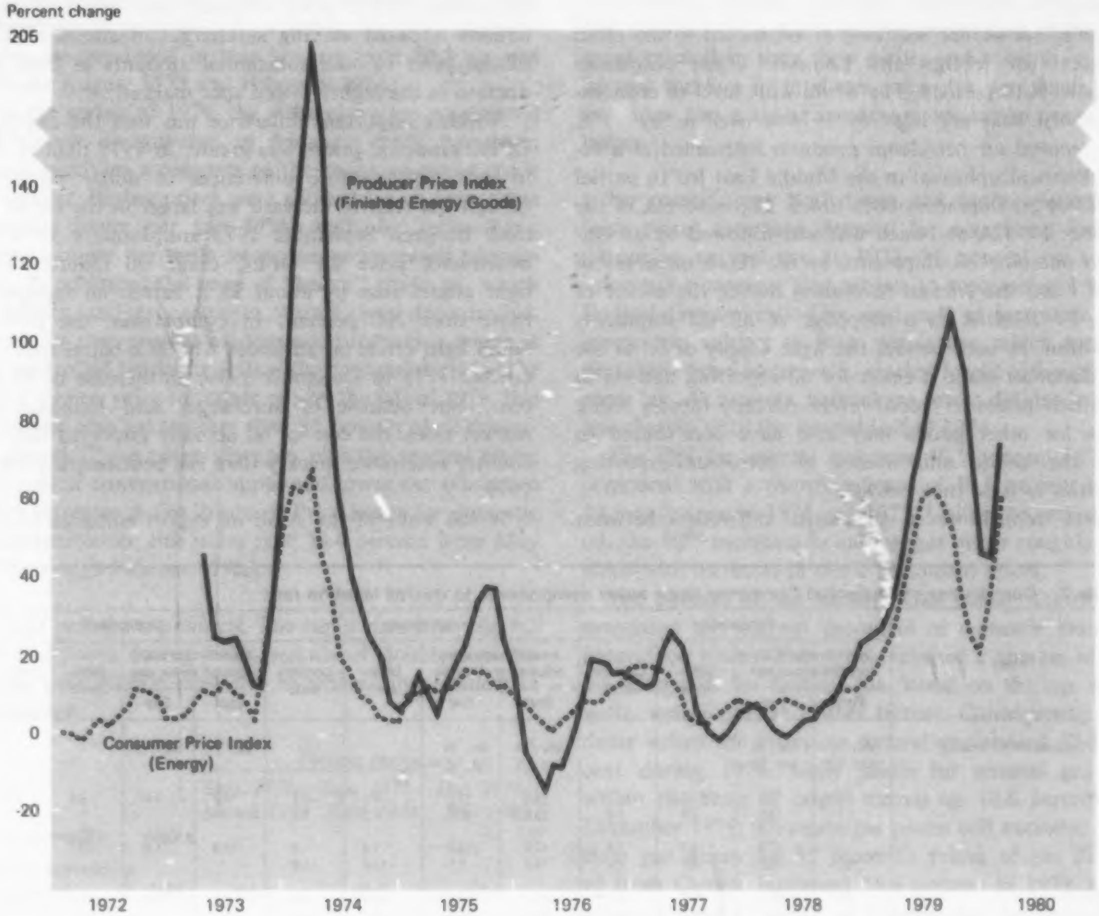
Food prices seemed to follow a pattern of their own during the 1977–79 period and are thus more difficult to integrate into the overall inflation picture. In each of these three years, food prices climbed sharply early in the year when unusually harsh winter weather damaged crops and disrupted normal transportation and distribution channels. Poor weather in the United States and in many other major producing countries early in the year also raised fears that summer and fall harvests would be inadequate. Food price inflation eased later each year as generally favorable growing conditions led to excellent harvests for many crops

During the acceleration phase of the current inflation, the food index accounted for about one-fourth of the acceleration in the All Items CPI, compared with one-third of the earlier acceleration. When the All Items inflation rate was on a high plateau from early 1979 into early 1980, food prices provided a major decelerating pressure. Food prices were rising at a rate of 5.6 percent in February 1980, considerably less than the 16.0-percent rate registered in March 1979. A more moderate winter in 1979–80 was an important factor in preventing the bulge in food price increases that had marked the previous three years.

As in the earlier period, energy prices did not begin to accelerate until some time after the All Items CPI had started to speed up. In the latter half of 1978, energy prices rose at an annual rate of 10 percent; but by mid-1979, energy prices were soaring at a rate of about 60 percent. Energy prices, like food prices, played a somewhat smaller role during the acceleration phase of the current inflation. But, unlike the earlier period, energy prices did not slow down as dramatically as they had speeded up; the energy CPI was still rising at a rate of 19.2 percent in the final quarter of the year. Another round of sharply higher prices for gasoline and home heating oil resulted in a much higher rate of increase for the energy index in the opening months of 1980, a situation without parallel in 1973–74.

In the remainder of this article, we examine some of the major factors that have helped to determine the course of double-digit inflation through both periods—the rapid rise in energy prices, the indirect effects of energy price increases, inflation in manufacturing materials, the role of food prices, the behavior of prices of

Chart 3. Inflation rates for retail and producer prices of energy, 1972-80[1]



[1] Three-month change seasonally adjusted at annual rates for Consumer Price Index for All Urban Consumers (energy) and Producer Price Index for finished energy goods.

other goods and services, capital equipment prices, mortgage interest rates, and house prices. Based on that discussion, our final section presents a detailed analysis of the inflation picture as of early 1980, noting those factors which are continuing to produce double-digit inflation, as well as other influences which may eventually slow inflation.

Energy prices explode

There were marked similarities in the timing of energy price increases relative to the two inflationary cycles. Sharp increases in world crude petroleum prices occurred on both occasions after inflation had already approached double-digit rates for other reasons. Prices for domestic crude oil also climbed sharply both times as controls were relaxed to encourage greater energy independence by spurring production and conservation. Prices for other forms of energy moved up sharply in the wake of higher crude oil costs. The added impetus of higher energy costs pushed the overall rate of inflation to its highest point.

The United States became increasingly dependent on imported crude petroleum during the 1970's. The ratio of imports to total domestic consumption of crude oil rose from 26 percent in 1973 to 45 percent in 1977. The import ratio has since varied between 40 and 45 percent. As a result, the cost impacts of OPEC price changes are now much greater than they were in 1973.

Crude oil. A similar sequence of events led to the rapid advances for foreign and domestic crude petroleum prices in both periods. The world-wide level of economic activity was very high by 1973 as well as by 1978, and demand for petroleum products intensified as a result. Political upheaval in the Middle East led to partial cutoffs of oil shipments both times. The outbreak of the October 1973 Arab-Israeli war was followed by an embargo on some oil shipments by the Arab members of OPEC, and the Iranian revolution during the winter of 1978–79 resulted in a stoppage of all oil shipments from Iran. In each period, the tight supply of oil in the world market made it easier for oil-exporting nations to raise their prices to record levels. Already rapidly rising prices for other goods may also have contributed to both the desire and ability of petroleum-exporting countries to raise their prices.

There were, however, substantial differences between the two periods. The price increase in 1973 was uniform for all OPEC members and was implemented at essentially one time. In 1979, by contrast, a number of increases were effected throughout the year, and the disciplined OPEC price structure was broken; several nations imposed varying surcharges in addition to the official price or sold substantial amounts of their production in the higher-priced spot market.

Another important difference was that the change in OPEC crude oil prices was greater in 1979 than in 1973 in terms of absolute differences of dollar prices, although the relative increase was larger in the earlier period. Between September 1973 and January 1974, the benchmark price for OPEC crude oil (Saudi Arabia light grade) rose by about $8 a barrel, an increase of more than 260 percent. In comparison, the price of Saudi light crude oil advanced $11.30 a barrel from December 1978 to December 1979, an increase of 89 percent. But because of surcharges and frequent spot market sales, the cost of oil actually imported into this country rose more quickly than the benchmark prices in 1979.[2]

In the wake of the Arab oil export embargo in 1973

[1] Entries in this column show how much of the difference in the rate of change for the All items CPI during each phase was accounted for by the difference in the rate of change for the CPI components shown.

[2] Computations are made as though the end of the All items CPI high plateau phase were February 1980. However, there is yet no evidence of any deceleration.

and the stiff boost in world oil prices, the Federal Government set higher prices for oil extracted from new wells and for any additional oil pumped from old wells in excess of the previous rate of production. Prices for oil from wells with very low yields (stripper wells) were completely decontrolled. As a result, the price of crude petroleum produced in this country rose 60.3 percent between August 1973 and February 1974.

In the spring of 1979, the Administration accelerated the phased deregulation of domestic crude petroleum prices, partly as a response to the changing world crude oil market. Higher prices were allowed for oil from some marginal lower tier (pre-1974) wells by reclassifying them as upper tier wells to encourage increased production. In addition, the price of "heavy" crude oil, which is difficult and expensive to extract, was decontrolled. Prices for that portion of domestic production which is not controlled tended to follow the continuing rise in the world market price for crude oil; by the fall of 1979, this share had climbed to more than 25 percent of all domestic output. These policy changes, plus the gradual lifting of prices of conventional upper and lower tier oil, led to sharp increases in the Producer Price Index for domestic crude petroleum; this index rose 53.4 percent from May 1979 through February 1980.

Refined petroleum products. The rapid rises in crude petroleum prices during both periods of double-digit inflation were quickly passed on by refiners and retailers to consumers:

		Percent increase		
Commodity	*Index*	*Sept. 1973– March 1974*	*Sept. 1973– Sept. 1974*	*Dec. 1978– Feb. 1980*
Refined petroleum products	PPI	56.2	85.2	85.1
Gasoline	PPI	49.9	73.6	84.1
	CPI	36.8	40.4	75.3
Home heating oil	PPI	68.4	101.2	85.6
	CPI	52.2	66.2	79.2

During the first surge of inflation, price increases for refined petroleum products were concentrated in the first 6 months following the steep boost in foreign crude oil prices in the autumn of 1973. In the current period, prices for refined petroleum products have been rising since December 1978, reflecting the series of increases in both domestic and foreign crude oil prices.

In both periods, prices charged by petroleum refiners advanced proportionately more than retail prices; however, there was a smaller difference between the relative increases at the primary market and retail levels in the current period. Dealers' margins have not climbed nearly as much as have the prices received by refiners. About three-fourths of the retail price of gasoline went to petroleum refiners at the end of 1979, while refiners only accounted for about half of the retail price before the 1973 energy crunch. Similarly, distributor margins for fuel oil are now a much smaller proportion of the total retail price than they were earlier. As a result, a given percent increase in producer prices for petroleum products now has a larger impact on consumer prices than before.[3]

Other energy items. Both times, the rise in crude petroleum prices increased demand for competing fuels, in particular, natural gas. In 1973–74, natural gas sold in interstate commerce was subject to strict control by the Federal Government. Gas sold only in intrastate commerce was subject to State regulation, which typically permitted price increases to market levels, although with some lag. As a result, natural gas prices did not begin to rise sharply until the second half of 1974.

The PPI for natural gas rose 40.9 percent in 1979, compared with a record increase of 49.6 percent over a 12-month span in 1974 and 1975. Unlike the earlier period, the 1979 increases in natural gas prices roughly coincided with increases in crude petroleum prices.

The passage of the Natural Gas Policy Act of 1978 mandated the gradual decontrol of domestic interstate natural gas prices. This act established a number of pricing categories for natural gas, based on the age of the wells, well depth, and other factors. Consequently, producer prices for interstate natural gas soared 57.3 percent during 1979, while prices for natural gas sold within the State of origin moved up 10.6 percent. (In December 1979, intrastate gas prices still exceeded interstate gas prices by 35 percent.) Prices of gas imported from Canada increased 58.8 percent in 1979, as the National Energy Board of Canada tied its natural gas export prices to the world market price of crude petroleum.

Electricity rates for household, commercial, and industrial consumers rose rapidly during both periods:

		Percent increase	
Electricity use	*Index*	*Sept. 1973– Sept. 1974*	*Feb. 1979– Feb. 1980*
Household	CPI	21.8	13.7
Commercial	PPI	26.5	18.4
Industrial	PPI	38.2	20.0

The slower rise in the current period may be attributable in large part to three factors: smaller increases in residual fuel oil prices; less reliance by electric utilities on residual fuel oil as a fuel; and all cost increases may not have been passed through yet to the consumer.

Indirect energy effects

In addition to higher prices for processed energy products, a rise in crude energy prices can produce two indirect effects: Price increases in commodities for which petroleum and natural gas are raw materials, and price increases associated with energy consumption in the production and distribution process.

Crude petroleum and natural gas are feedstocks for a wide variety of chemicals which, in turn, are employed in the manufacture of thousands of goods. Table 3 illustrates some of the more significant impacts. The chemicals listed as petroleum-based are either primary ones which are largely produced as part of the petroleum refining process (benzene and toluene), or are derived from such chemicals. The exception is ethylene, which also has a substantial amount derived from natural gas liquids.

Natural gas liquids serve as the primary source for another series of chemicals which are not, however, entirely independent of petroleum feedstocks. In addition, the ammonia base for nitrogenous fertilizers is derived from natural gas.

As effects of the 1973 OPEC oil price boosts were appearing in prices for refined petroleum products, prices for primary chemicals such as benzene and toluene were also increasing, but at much more rapid rates. Prices for the more highly processed chemicals such as styrene monomer and acetone reached their maximum rates of increase about 1 quarter after the peak for primary chemicals and began to slow between 1 and 2 quarters after the prices of primary chemicals. Reflecting its partial dependence on natural gas, prices for ethylene rose more slowly than prices for other petroleum-based chemicals in early 1974 but continued to rise rapidly into 1975 as natural gas prices accelerated in the second half of 1974. Prices for other natural-gas-related chemicals and nitrogenous fertilizers also rose more slowly and for a longer time as the result of the different timing in natural gas price changes.

During 1978 and 1979, there was less difference in the timing of price changes for petroleum and natural gas. As a result, prices for the two series of chemicals demonstrated greater similarity in their timing. Nevertheless, those with a substantial natural gas component have registered smaller price rises. For both series of chemicals, price increases during the current period have not been as sharp; however, large increases are

generally continuing for a much longer time.

Plastic resins are polymerizations of chemicals from both the petroleum series (such as styrene monomer) and the natural gas series (such as vinyl chloride). During both periods, prices for plastic resins generally reflected the increases in the corresponding raw materials within one quarter. As much as one more quarter was required before prices of plastic products made from the resins reflected the maximum effect of the raw materials price increases. As prices for petroleum-based chemicals began to decline in late 1974 and the first half of 1975, prices for plastic resins and plastic products also began to fall. At the start of 1980, however, prices for plastic products began to slow despite the fact that prices for plastic resins and their constituent chemicals were continuing to post rapid increases.

Both synthetic and natural rubbers are used in the manufacture of tires. The doubling of natural rubber prices in 1973 was the primary cause of the 27.3-percent rate of advance in producer tire prices during the last quarter of 1973. Synthetic rubber prices soared during the first half of 1974 as the result of crude oil price increases. These price jumps for both kinds of rubber led to a 53.9-percent annual rate of increase in producer prices for tires during the first quarter of 1974. Retail tire prices, in turn, rose at double-digit rates until late 1974, when the depressed auto market lowered new-car demand for tires, and tire price rises slowed.

Price boosts for synthetic rubber were not as sharp in the more recent period. They were once again compounded by large price increases for natural rubber, which, however, were also smaller than before. Consequently, tire prices have risen more slowly. Although demand for new automobiles dropped in late 1979, overall consumer demand remained strong enough to enable manufacturers to pass along increases in raw materials prices.

Textiles and apparel. Cellulosic fibers are only slightly dependent on petroleum feedstocks. Noncellulosic fibers, on the other hand, are almost exclusively petroleum-based. In 1973–74, however, noncellulosic fibers showed only modest increases, while cellulosic fiber prices climbed at a double-digit rate. During the current period, prices for noncellulosic fibers did exhibit some greater impact from rising oil prices, although these increases were well below those for other petroleum derivatives.

During both periods, textile prices were under cost pressure not only from petroleum-based synthetic fibers but also from rapid price jumps in raw cotton. Nevertheless, during 1979 prices for finished fabrics rose only 3.1 percent, and prices for apparel (other than footwear) were up only 4.4 percent at the manufacturers' level and 3.8 percent at retail. In 1974, textiles and apparel prices also experienced less-than-average increases.

Why prices for textiles and apparel should exhibit such apparent resistance to cost pressures from raw materials is a topic that deserves further research. A number of factors, however, may contribute to this phenomenon. The apparel industry is composed of a large number of highly competitive firms, although competition may often be reflected in product differentiation as well as in price. In addition, there is substantial competition from imports. Demand may well be fairly price elastic, because a substantial proportion of clothing expenditures may be discretionary.

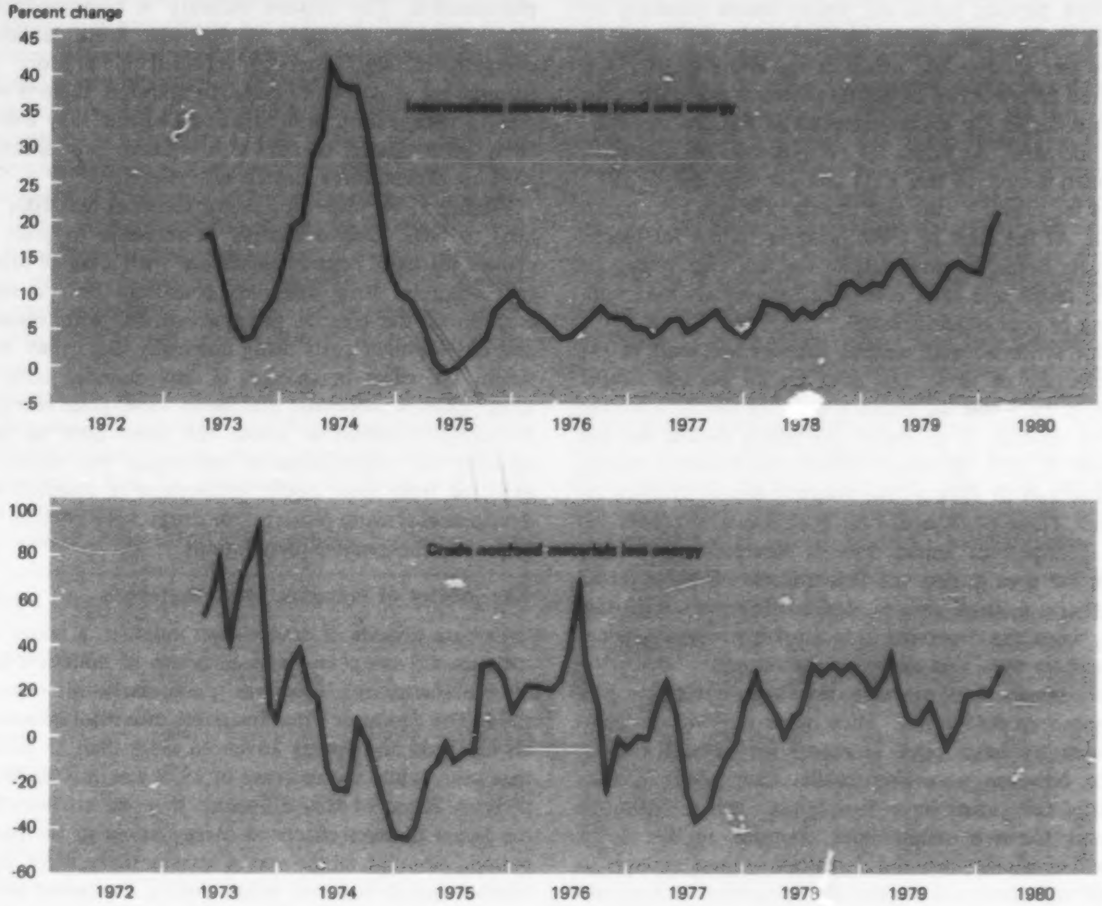
During 1974, prices for pharmaceutical materials appear to have jumped sharply in response to price increases for basic organic chemicals, with a lag of one or two quarters. Raw materials constitute only a small fraction of the cost of pharmaceuticals, with research and development costs being unusually important. As a result, the effect of changes in raw material costs on drug prices is somewhat muted. In 1974, price increases for drugs occurred at about the same time as price changes for pharmaceutical materials. As would be expected from their higher proportion of research and development costs, prescription drugs were affected less than over-the-counter preparations.

The impact of manufacturing materials

In both periods of double-digit inflation, a major factor was the sharp increases in prices of materials used in manufacturing. This was particularly the case in 1974. The Producer Price Index for intermediate materials less food and energy advanced more than 25 percent that year, while the increase in 1979 was just under 13 percent. Some of this difference may be attributed to the larger indirect effects of energy prices in the earlier period. Another factor was a substantially more rapid climb in crude material prices during the earlier period which began before the jump in crude petroleum prices. Prices for crude nonfood materials less energy were climbing at a rate in excess of 80 percent for the 6 months ended in September 1973, compared with a peak rate of 32.5 percent for the 6 months ended in March 1979. (See chart 4.)

Much of the inflation during 1973–74 had its origins in a worldwide commodity price boom that began in late 1972, which has had no counterpart in the more recent period. In addition, price controls kept prices for many items artificially low, thereby contributing to shortages of several materials. As controls were removed, industrial material prices rose unusually rapidly. Reflecting the vigorous state of the world economy, as well as the reduced value of the dollar in international money markets, price increases accelerated sharply for a broad range of basic materials, such as scrap metal, natural rubber, inedible fats and oils, woodpulp, and wastepaper.

Chart 4. Inflation rates for intermediate materials and crude nonfood materials, 1973-80[1]



[1] Three-month changes seasonally adjusted at annual rates for the Producer Price Indexes for intermediate materials less food and energy and for crude nonfood materials less energy.

The steel and nonferrous metals industries are two of the heaviest consumers of energy in manufacturing, and in both periods prices of their products were affected by runups in energy prices. (See table 4.) Very strong demand and rapid increases in scrap metal prices also contributed to price increases for metals.

Scrap metal prices are very sensitive to demand and thus are a barometer of the demand for metals. However, as a major raw material in metal production, scrap metal prices also represent a cost of manufacture. During 1973, strong demand and material shortages drove prices of primary and scrap metals up sharply. By the first quarter of 1974, higher prices for fuels added to the cost pressure. By the second quarter of 1974, demand for nonferrous metals began to fall off, depressing prices for nonferrous scrap; rising fuel costs continued to push up primary nonferrous prices at annual rates in excess of 50 percent. By the end of the third quarter, most fuel costs had been passed through, and nonferrous metal prices began to fall in response to declining demand.

In 1974, steel manufacturers also passed on higher fuel costs during the first half. But steel demand remained strong most of the rest of the year, largely because of heavy demand from capital equipment

manufacturers. Prices continued to rise into 1975 as a result.

In 1978 and early 1979, strong demand for both ferrous and nonferrous metals kept prices for metal scrap rising rapidly, although not as spectacularly as in 1973. Unlike the second half of 1974, however, the second half of 1979 saw considerable slackening in demand for steel. This reduction in demand, coupled with the impact of the Administration's price guidelines, helped to keep the rise in steel prices smaller than in the earlier episode. Increased fuel costs undoubtedly contributed to the continuing steel prices increases. Steel prices were also affected by the Government's "reference pricing system" which placed a floor under imported steel prices through the use of anti-dumping duties triggered by a set of reference prices.

In contrast to 1974, nonferrous metal prices also have continued to rise rapidly. The effects of increased energy costs have been matched or exceeded by a number of other factors that were not present in 1974. Speculative demand drove prices for gold and silver up more than 200 and 600 percent over the 12 months ending in January 1980. Speculation spilled over into other metals, especially copper, which rose nearly 50 percent in the same period. (Other commodities such as sugar, natural rubber, and raw cotton were also affected by speculation.) Cobalt prices quadrupled during 1978 and 1979 because of political violence in Zaire, the world's leading producer.

The case of new cars. During both periods, new car prices were pushed upwards by the direct and indirect effects of the drop in the value of the dollar in international money markets. Prices of imported cars were raised to offset the dollar's decline; these increases in turn allowed domestic producers to boost prices of those models which were in high demand because they were most competitive with imports in terms of size and mileage. Both periods later witnessed a drop in demand for larger new automobiles in response to the uncertainties of gasoline supply and higher gasoline prices. In the early months of both 1975 and 1980, manufacturers established substantial rebate programs to stimulate demand.

Price behavior of new cars each time, however, was quite different. During the 12 months ending in February 1975, new car prices rose 11.5 percent, compared with 8.0 percent for the 12 months ending in February 1980. The earlier increase was larger, partly because, as noted, steel prices rose more rapidly. Some of the slower rise in the current period might also be attributed to the Administration's price guidelines. The slower recent advance came in spite of the fact that demand for new cars remained stronger than in 1975; auto production has remained well ahead of its 1975 levels. The stronger demand currently may partly reflect the automobile industry's restructuring of its product line since the mid-1970's, improving gas mileage substantially on existing car lines and introducing more small-car models.

Distribution costs rise

Petroleum products, of course, are used heavily in the distribution of goods, including transportation and the operation of retail outlets. The intermediate energy goods and crude fuel indexes in table 4 show the rising costs from energy faced by the distribution process.

The railroad freight rate index illustrates the impact of fuel cost changes on transportation charges. The regulatory process usually permits some immediate relief to carriers for fuel cost increases. However, the full impact usually seems to come 3 to 6 months later.

The effects of fuel costs on the distribution process are illustrated by the prices for food at home. (See chart 2.) Through the first part of 1976, the over-the-year percent change in that CPI component had mirrored changes in the PPI for consumer food in a very regular way: major changes in the two indexes occurred either simultaneously or within a month or two of each other, and prices received by food processors both accelerated and slowed more quickly because retailers and wholesalers tended to absorb some of the increases and recoup them on the down side. Retailers infrequently evaluated and incorporated changes in overhead costs into pricing decisions.

The energy price runup of 1974 changed all of that. It took a couple of years for retailers to adjust. But, since the beginning of 1976, food price increases over 12-month periods have usually been larger for the CPI than for the PPI, both when food prices were accelerating and when they were decelerating. While these data do not readily yield an estimate of the price impact of energy on the food distribution chain, they clearly suggest an increasing influence of energy on food prices which dampens the effect of falling producer prices on retail prices.

Increases other than food and energy

Substantial indirect energy effects on prices of consumer commodities other than food and energy began to be reflected in the PPI during the first quarter of 1974. (See table 4 and chart 5.) As we have noted, the end of price controls, strong demand, and worldwide inflation in a number of basic materials also caused manufacturers' prices to accelerate through the second quarter. As both energy prices and demand began to slow in the second half of the year, increases in producer prices for finished goods other than food and energy decelerated, reaching a 3-month annual rate of only 2.3 percent by the middle of 1975.

Retail prices for commodities other than food and energy rose somewhat more slowly than at the producer level, hit their peak about one quarter later, and decelerated more slowly. Prices for consumer services other than energy followed the same pattern with still smaller increases and less pronounced deceleration.

Currently, retail and manufacturers' prices for nonfood commodities other than energy have moved even more closely together. The major exception was in early 1980 when sharp PPI rises for fine jewelry and silver flatware were not reflected as strongly in the CPI. Prices for goods other than food and energy have risen more slowly this time. On the other hand, their period of rapid increases has been more protracted, and the indirect impacts of the last two OPEC price increases have not yet filtered through.

In addition, demand seems to have been fueled by a psychology of inflationary expectations in which consumers have made purchases out of fear that prices will be still higher in the future. As a result, by recent standards personal savings rates have reached new lows, and consumer debt has hit new highs. Speculation in basic materials has also served to extend the inflationary period, and the final effects from that still have not reached the consumer.

Unlike the earlier period, the index for nonenergy service prices has risen faster than commodity prices and has continued to accelerate to rates higher than those reached in 1974. This difference can be traced to the effect of mortgage costs, which have accounted for about half of the increase in this index. The record-high mortgage interest rates in turn are the result of the overheated economy and the elevated demand for consumer credit to finance the inflation-induced demand, as well as significant steps taken by the Federal Reserve Board to restrict credit. Because of the lag from the time a house buyer contracts for a mortgage until settlement, the maximum impact from the recent runups in mortgage interest costs has not yet been reflected in the CPI.

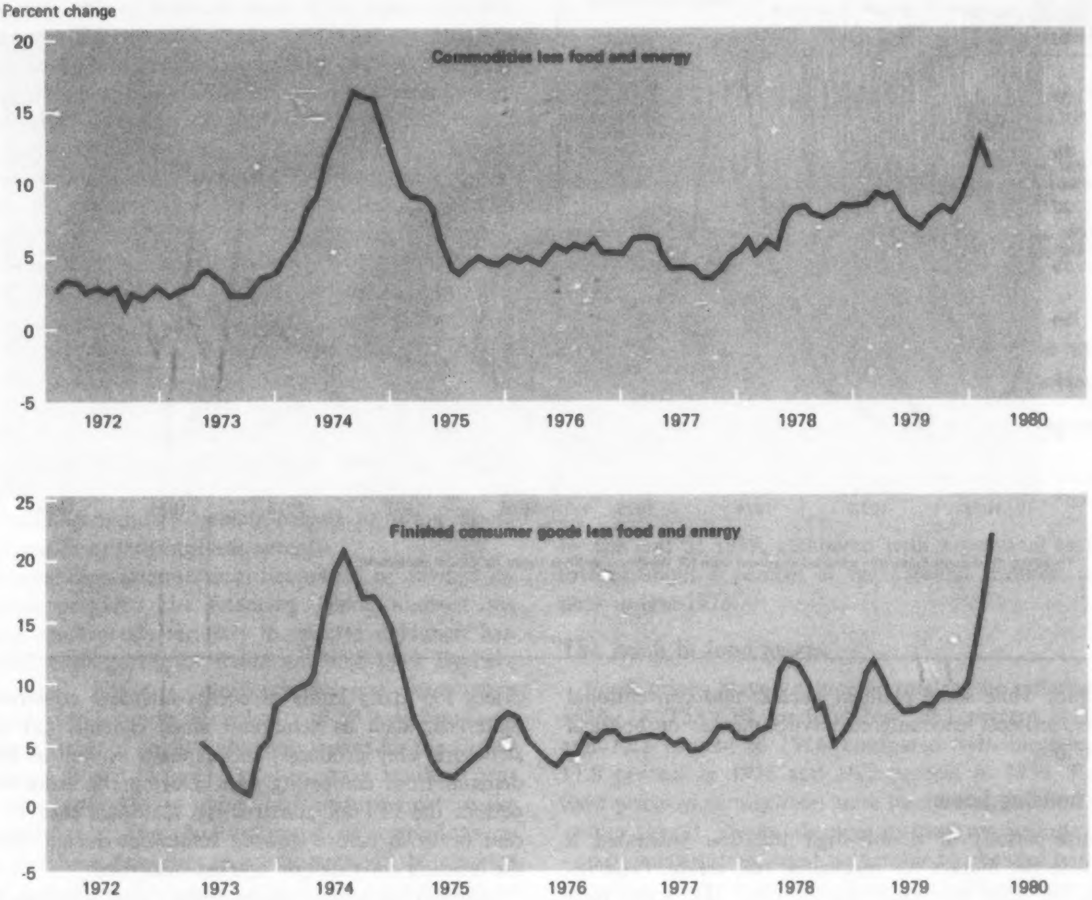
Capital equipment. Producer prices for capital equipment advanced at a much faster rate in the first round of double-digit inflation. (See table 4 and chart 6.) After rising 5.3 percent in 1973, this index jumped to a 14.3-percent rate in the first quarter of 1974 and rapidly accelerated after the April 30 expiration of the price controls program to a rate of about 30 percent in the third quarter. This index was still climbing at a 13-percent rate as late as the first quarter of 1975, at the bottom of the recession. In contrast, the rate of increase in capital equipment prices peaked at a rate of no more than 11 percent in early 1979 and rose 8.7 percent for the year as a whole, only slightly more than the 8-percent increase registered in 1978.

The 1974–75 spurt in the capital equipment index was in two ways a reflection of capacity shortages in many materials-producing industries. On the one hand, these shortages produced sharply increased demand for many types of industrial equipment; on the other, they drove up prices for the major materials used in the manufacture of capital equipment.

The absence of a similar widespread capacity crunch more recently helped to moderate capital equipment inflation, as the rate of growth in the general economy did not prove excessive compared to the Nation's capital stock. The relatively slow rate of recovery in capital expenditures after the last recession had raised concerns that the economy would soon be constrained by an inadequate supply of investment goods. Rather than commit themselves to long-term capital projects which might lead to excess capacity, many producers attempted to prolong the useful life of existing plants and equipment; one consequence was increased demand for replacement parts and thus a rapid rate of inflation in their prices.

Special factors contributed to changes in the rate of inflation during the 1970's for some types of capital

Chart 5. Inflation rates for consumer goods, less food and energy, 1972-80[1]



[1] Three-month changes seasonally adjusted at annual rates for the Consumer Price Index for All Urban Consumers for commodities less food and energy, and the Producer Price Index for finished consumer goods less food and energy.

equipment. The drive to make America less dependent on foreign energy sources, for example, kept prices for most kinds of capital associated with the energy exploration and production industries advancing rapidly from 1973 through the end of the decade, even during times when prices of most other investment goods were rising slowly. Prices for agricultural and construction machinery were somewhat sensitive to shifts in the level of farmers' income and construction activity. Prices for machine tools rose at unusually steep rates during much of the 1978–79 episode, in part because of intense demand from the motor vehicles industry generated by the need to produce downsized models with improved fuel efficiency; heavy demand from the aerospace industry was another important influence.

In contrast, motor truck prices rose much less in the current period, partly because demand for light trucks and vans with relatively low gas mileage dropped greatly in the wake of the steep rise in gasoline prices in mid-1979. Demand for capital goods by electric utilities was restrained as some expansion projects were postponed or canceled; sharply higher electricity rates led to increased consumer conservation efforts, thereby lowering the long-range projections of growth in electricity

demand, while some planned nuclear and conventional power projects encountered environmental or political objections.

The housing boom

Both periods of double-digit inflation witnessed a boom in the market for residential real estate. Price indexes for both mortgage interest rates and home purchase started to accelerate around mid-1973, more than a year after rising food prices had initiated the acceleration in the All Items CPI. From July 1973 through October 1974, the CPI for mortgage interest rates moved up 21.4 percent. Home purchase prices also started to advance more rapidly in mid-1973 and continued to rise at a steep rate for nearly 2 years; by May 1975, this index was 21.9 percent higher than in July 1973. During the current inflation, home purchase prices and mortgage interest rates have again soared. Between December 1977 and February 1980, the index for mortgage interest rates increased 35.3 percent; the home purchase index climbed 30.5 percent during the same span.

Rising construction material costs were an important influence in the home price surge of 1973–74, but may have been less crucial in the current period. In the year ended September 1974, the Producer Price Index for construction materials and components advanced 23.6 percent. This steep rate partly reflected sharply higher prices for many kinds of energy-intensive construction materials, such as structural steel, cement, flat glass, structural clay products, and asphalt, as well as strong demand from competing uses. During the more recent period, the PPI for construction materials rose 11 percent in 1978, before slowing somewhat during 1979 as the housing construction market weakened.

Demand for homes was extremely strong during most of the 1970's, partly because of a rapid growth in the number of people in the age and income categories most interested in buying a first home. The rate of residential construction starts peaked in October 1972 at more than 2.4 million units, as ample funds were available to accomodate the intense demand. (See table 5.) But as the general economic boom continued, tighter conditions began to prevail in the money markets. The resulting record-high interest rates reduced the availability of home mortgage financing. This was a major factor in the virtual collapse of the homebuilding industry by late 1974 and early 1975, when construction of new private housing units sank to less than one million. As housing starts reached this depressed level after 2 years of decline, interest rates dropped quickly, and home purchase prices began to rise much more slowly.

The residential construction market recovered gradually from its depressed level of early 1975, as mortgage funds became generally available again. By 1978, the annual rate of new private home construction exceeded the 2-million unit mark in spite of the renewed climb in interest rates. Although a marked drop in construction activity was widely anticipated for 1979, the housing market was able to maintain most of its vigor until late in the year. The strength of the residential construction market in the late 1970's, in part, reflected several institutional changes, combined with the development of an inflationary psychology among many prospective home buyers.

New regulations allowed savings institutions (traditionally the primary source of mortgage financing) to issue money market certificates as of mid-1978, which paid an interest rate approximately equal to that of six-month Treasury bills. This action allowed savings institutions to compete more effectively for investment capital. This prevented "disintermediation," which had often occurred late in a business expansion when rising interest rates induced investors to purchase high-yield certificates rather than deposit funds in savings and loans, where interest rates were kept down by law. In the past, disintermediation led to recessions in the homebuilding industry, which helped to bring about downturns in overall business activity.

The new high-interest securities issued by savings institutions provided the financing which allowed the housing construction industry to operate at higher than expected levels during 1978 and much of 1979. By February 1980, however, mortgage interest rates were climbing at a 3-month annual rate of 33.9 percent—reflecting a series of credit-tightening moves by the Federal Reserve Board in early October. As a result, it was no longer profitable for many thrift institutions to make mortgage loans. The resulting cutoff or restrictions on home purchase financing in many parts of the country led to a drop in the rate of new home construction to an annual rate of approximately 1.5 million units at the beginning of 1980. As in 1973–74, home purchase prices and interest rates continued to climb many months after the rate of residential construction had begun to decline.

Another reason why the housing market maintained its strength longer than had been generally expected was that homes became more attractive as an investment. Inflationary expectations led many people to shift their assets from savings to home equity. From June 1978 through December 1979, the CPI for home purchase rose about 23 percent, compared with an advance of about 18 percent for the All Items CPI. Because home values were generally rising faster than the overall inflation rate, home purchases were widely viewed as a hedge against inflation. The consequent high demand for houses served to push prices up further and reinforce the initial perception. This was one reason the aggregate personal savings rate fell to about 3.5 percent by the end of 1979, compared with a personal savings rate of about 8 percent at the previous business cycle peak in late 1973.

Table 5. Timing of selected business cycle indicators and the Consumer Price Index

Business cycle indicator	1973–74		1978–79	
	Lead time[1]		Lead time[1]	Date of high value preceding Feb. 1980
	Trough to acceleration start	Peak to deceleration start	Trough to acceleration start	
Gross National Product, 1972 dollars	–18	–11	–32	([2])
Personal income, 1972 dollars	–18	–12	–28	Dec. 1979
Employees on nonagricultural payrolls	–18	0	–30	([2])
Industrial production index	–18	–4	–31	Mar. 1979
Capacity utilization	–18	–14	–32	First quarter 1979
New orders for nondefense capital goods, 1972 dollars	–19	–3	–28	Mar. 1979
New housing starts	–28	–24	–32	Apr. 1978
Ratio of deflated inventories to sales, nonmanufacturing and trade	–18	–20	–31	([2])
Corporate bond yields	–4	–1	–10	([2])
Ratio of consumer installment credit to personal income	–11	–8	–24	Sept. 1979
Index of four roughly coincident indicators	–18	–11	–31	Mar. 1979

[1] The number of months by which the trough or peak of the given business cycle indicator leads (negative value) the start of acceleration or deceleration in the All Items CPI.

[2] These indicators were still rising at the time of the most recent available data.

The jump in food prices

Food prices played a greater role in the inflation of 1973–74. The CPI for food rose 20.1 percent in 1973 and 12.2 percent in 1974, compared with increases of 11.8 percent in 1978 and 10.2 percent in 1979. Retail food prices generally rose more moderately in the intervening period. Sharp advances in food marketing costs—particularly those most vulnerable to changes in energy prices—were a major influence in both periods; food processing and marketing currently account for about two-thirds of retail food prices.

Both periods were characterized by the declining value of the dollar on international exchange markets. The real value of agricultural exports expanded more than 60 percent from 1972 through 1979, partly because of the lower value of the dollar in international money markets. As a result, the relative proportion of agricultural exports to total cash receipts for farm products increased over the decade; more than 25 percent of all total cash receipts for farm products were accounted for by exports in 1979, compared with a 15-percent share in the early 1970's.

Beef prices were highly volatile in both periods as cattle owners initially attempted to liquidate herds that were no longer profitable. Smaller cattle herds led to higher beef prices, which encouraged consumers to shift demand to less expensive substitutes, such as pork, poultry, and cheese, resulting in higher prices for these items. Price trends for beef tend to last longer than trends for pork and processed poultry prices; because the production cycle for cattle is longer, adjustments in beef output to changing market conditions are slower. In both cases, high cattle prices eventually induced farmers to increase their cattle herds. In 1974, this produced declines in beef prices. In the current period, herd rebuilding has only recently begun.

Unfavorable weather conditions reduced grain supplies in several foreign producing countries in 1972 and early 1973. Curtailed harvests in these countries, particularly the Soviet Union, and scarce supplies of soybean and Peruvian fish meal caused an upsurge in export demand for U.S. grains. From July 1972 to October 1973, grain prices soared 137.8 percent and manufactured animal feeds, 166.4 percent.

To alleviate the situation of tight supplies and increasing prices of grains and grain products in 1973 and 1974, changes were made in various Government farm commodity programs in an effort to expand domestic crop production and supplies. The Federal Government liquidated virtually all of its stockpiles of major grains. Direct export subsidies for all agricultural commodities were terminated. Export restrictions were placed on soybeans and cottonseeds in 1973.

Grain prices declined from late 1974 through mid-1977, so that they were only half as high at the end of this period as they were at the beginning. On balance, there were favorable growing conditions in grain-producing countries. In 1976, domestic production of both wheat and corn was at record levels. Carryover inventories of grains at the start of the 1976–77 growing season were at the highest level in 20 years, reflecting lower exports. Grain prices then rose for most months from mid-1977 through the end of 1979, although at rates well below those of the first period. The PPI for grains was more than 60 percent higher in December 1979 than in August 1977. The Federal Government's program of farmer-owned grain reserves and increased construction of on-farm storage facilities permitted farmers to withhold corn and wheat from the market and thus kept prices rising in spite of excellent domestic harvests. Strong export demand was another key influence.

Among other foods, retail prices for sugar and sweets soared 130.9 percent from January 1973 to January 1975, as raw cane sugar prices quadrupled. The unusually sharp increases were caused by several factors, such as a poor harvest of European sugar beets, typhoon damage to Philippine sugar cane crops, strong demand in world markets, and the uncertainty of U.S. purchasing policies due to the expiration of U.S. sugar price supports. Over the next 2 years, however, these prices declined as output expanded in the face of buyer resistance. Prices for sugar and sweets turned up again in January 1977 and continued to rise through the rest of the decade, although not nearly as rapidly as in the earlier price boom.

Retail roasted coffee prices more than tripled from mid-1975 through mid-1977, reflecting first the effects of the severe 1975 Brazilian freeze and, later, the effects of production problems in Guatemala and Angola. This index declined by one-third from mid-1977 through mid-1979, as output gradually expanded and consumers cut consumption in reaction against higher prices. Prices turned up for the rest of 1979, partly because of adverse weather in Brazil and political turmoil in Nicaragua.

The current situation

It would be risky to develop any generalizations about the way double-digit inflations end from a single recent example. Nevertheless, it is the only comparable case available. Noting the similarities and differences between then and now will at least help to define the situation as of early 1980 and point to the factors to be watched in the coming months.

One of the major factors contributing to the rapid deceleration of prices in 1974–75 was the severe recession that accompanied it. The recession has been officially designated as beginning in the fall of 1973 at about the time that the Gross National Product, real personal income, and capacity utilization turned down. It remained mild, however, until late in 1974, after employment, industrial production, and new orders for nondefense capital goods all had begun to decline. Prices began to decelerate only after the recession entered its most depressed months. (See table 5.)

Although a number of forecasters have been predicting a recession for some time, the evidence is still not conclusive that one has begun. Industrial production, new orders for nondefense capital goods, and capacity utilization are all below first-quarter 1979 levels, and real personal income declined during the first two months of 1980. But the Gross National Product and employment, the two most significant indicators of a recession, have not begun to decline.

A severe recession need not be the only way to bring double-digit inflation down. Nevertheless, the single example of 1974–75 suggests that prices are slowed as the result of declining demand only when the reduction is substantial and prolonged. As of February 1980, little price relief from this source could be expected in the near future. The indicators in table 5 are those to watch for signs of slowing demand pressure on prices. Even if such relief were to come, it could well be partly or entirely offset by other factors.

One of the most important factors is the price of crude petroleum. There was a sudden rise in imported crude petroleum prices in late 1973–early 1974; by the second quarter of 1974, energy prices at all stages of processing were decelerating. Six months later, the secondary effects on other products were sufficiently attenuated to permit prices to begin slowing down as the general recession intensified.

During 1979, the situation was quite different. Although the increases in OPEC oil quotations were slower, OPEC raised its prices several times during the year. In addition, domestic energy prices are now less insulated from the world price of petroleum for a number of reasons: imports constitute 45 percent of all crude petroleum, compared with 26 percent in 1973; prices of domestically produced crude petroleum have been partially decontrolled and about one-fourth is now sold at approximately the world price; and price controls on natural gas have been relaxed somewhat since 1974.

Unlike 1974, crude and intermediate energy prices accelerated for about one year and did not begin slowing until October 1979. Even then, the slowdown, especially for crude energy, has been only modest. Imported crude petroleum prices are not included in this index, and the two most recent OPEC price increases have not yet been totally reflected in intermediate or finished products. In addition, OPEC is now reviewing its prices quarterly, and future actions cannot be anticipated. As a result, if reduced demand should begin to exert a slowing effect on prices during the early spring of 1980, the offsetting pressure from the attempts to pass through rising energy prices will be greater than they were in 1974.

Currently, cost pressures from crude and intermediate materials other than food and energy may be more protracted. In 1973 and 1974, prices for crude nonfood materials began to decelerate sharply 1 full year before the All Items CPI started to slow down; prices of intermediate nonfood materials did so 2 months before the CPI, with a very sharp deceleration thereafter. In 1979, prices for crude nonfood materials except energy began a deceleration in April, which would have been consistent with a slowdown for the CPI during the early spring of 1980. Unfortunately, these prices accelerated sharply beginning in October and had reached an annual rate exceeding 30 percent by February 1980.

The PPI for intermediate materials less food and energy stopped accelerating in early 1979. Unlike the rapid deceleration that occurred in 1974, prices in 1979 continued to rise at an annual rate of about 13 percent for the remainder of the year. Although the increases were only about half as fast as in 1974, they began to accelerate further during the first 2 months of 1980, even if the effects of gold and silver speculation are removed. However, to the extent that the acceleration in both crude and intermediate materials may also be affected by speculation in commodities such as cotton, rubber, and copper, it could collapse very quickly if demand drops.

Food prices are already a more moderating influence on the overall rate of inflation than was the case just prior to the deceleration phase in 1974. Retail food prices were 7.3 percent higher in February 1980 than 12 months earlier, while prices at the primary market level were up less than 3 percent. In addition, carryover supplies of most crops are extremely good, and cattle herds, though small, are beginning to expand. Of course, weather and foreign purchase plans can shift suddenly and change the price picture.

The stringent credit-tightening measures announced by the Federal Reserve Board in October 1979, followed by even greater tightening in March, are much more restrictive than any monetary actions in 1973–74. Interest rates may have a number of different impacts on overall price levels. On the one hand, higher interest rates are a cost and push prices higher. On the other hand, by discouraging debt-financed purchases they dampen demand and exert a slowing effect on prices. In this connection, rising interest rates during 1979 finally stopped the growth of installment credit as a proportion of personal income in September. In 1974, a similar drop in consumer credit preceded overall price deceleration by 8 months. If a comparable mechanism is present now, reduced consumer borrowing should exert slowing pressure on prices during the first half of 1980.

Interest rates on mortgages have a substantial impact on the CPI. Rapid rises in mortgage interest rates during late 1979 and early 1980 are among the most significant causes of continuing high inflation. However, high house prices and high interest rates have both had a depressing effect on the demand for housing. New housing starts have been falling since April 1978. During the earlier round of double-digit inflation, there was a two-year lag between the initial decline in housing starts and the deceleration of the CPI. A similar development this time would place the decelerating effect of house prices in the spring of 1980. In addition, a significant drop in aggregate demand would reduce the demand for borrowed funds and bring down mortgage interest rates.

Finally, there is the matter of the pressure which rising wages may have on prices, both from the demand side and from the cost of production. When prices began to decelerate after October 1974, hourly earnings (as measured by the average hourly earnings index for the total nonfarm sector) had increased 9.1 percent the previous year. As of December 1979, hourly earnings were 8.3 percent above their year-ago level. While these data suggest that wage pressures are not as severe now as they were during the earlier period, this proposition can be accepted only with two cautions. First, the higher 1974 rate (9.1 percent) was the result of a sudden runup from 5.8 percent at the end of 1972, while the current 8.3-percent rate is a continuation of the 7.5–8.5-percent range that has prevailed since 1975. Second, the lower rate may conceal a large pent-up demand for higher wages that may erupt later.

The cost of labor in the production process can be affected by two other factors as well: the cost of nonwage compensation and changes in productivity. The combined effects of wages, other compensation, and productivity are reflected in the unit labor cost data. These data show that because of more severe declines in productivity, unit labor costs were also placing greater immediate pressure on prices during 1974, increasing by 14.8 percent that year, compared with 11.1 percent in 1979.

In summary, we can make the following characterizations about double-digit inflation in 1973–74 and today:

> *Energy* prices were a major factor in both periods. Currently, price increases have been much more protracted, and both direct and indirect effects of crude petroleum prices have not yet been fully felt by the consumer. Future changes are heavily dependent on OPEC pricing decisions.
>
> *Food* prices led the acceleration both times but are currently a moderating influence.
>
> *Manufacturing material* prices rose much more sharply in 1973–74. Although there were some indications in 1979 that crude material prices had slowed, speculation and strong demand renewed their rapid increase.
>
> *Nonfood finished commodities other than energy* had substantial price increases in both periods as the result of higher raw material and energy costs, coupled with strong demand. Currently, cost pressures are still being felt, and slackening in demand has been too small to have had a major impact. Inflationary expectations have buoyed demand, increasing consumer debt and reducing the personal savings rate.
>
> *Mortgage interest and house prices* pushed inflation up sharply in both periods. A decline in the housing market beginning in late 1972 led to a slowing of house price rises in 1975. The housing market has been declining again since the spring of 1978. Mortgage interest rates are currently being pushed to record levels, partly as the result of Federal Reserve credit-tightening actions. ☐

FOOTNOTES

[1] The dates we have chosen for each phase are those appropriate for the Consumer Price Index for All Items for All Urban Consumers (CPI-U). To help reduce the effects of "statistical noise" in the data, annualized rates of change over 3-month spans are used throughout our analysis, unless otherwise specified. Seasonally adjusted data have been used for those time series exhibiting a pattern of stable seasonality.

[2] Through the first 9 months of 1979, the acquisition cost of imported oil climbed 67.7 percent, compared with a rise of 41.7 percent in the benchmark price. As 1980 began, the benchmark price was raised by an additional one-third retroactive to October 1979, and by another 8.3 percent effective in January 1980. OPEC decided to review crude oil prices every 3 months in the future.

[3] In both episodes, the Federal Government controlled gasoline prices at all levels, whereas fuel oil prices were decontrolled in 1976.

Measuring wage relationships among selected occupations

Occupational wage spreads, as measured by survey averages, do not mirror relationships within individual firms; pay differentials are much smaller within establishments

VIRGINIA L. WARD

Reviewers of occupational wage relationships should not be misled by averages derived from wage surveys. An analysis of data from the Bureau of Labor Statistics' area wage surveys[1] confirmed that nationwide relationships may have little or no similarity to those within individual establishments.

Inter-establishment averages are the basic product of the Bureau's occupational wage surveys. However, these averages tend to mask actual intra-establishment pay relationships. For example, in South Bend, Ind.,[2] during March 1976, average weekly earnings of class B secretaries were $165.50 and of class D secretaries (the lowest level studied that year), $167.50. This inverse relationship indicates that, in South Bend, establishments paying high wages employed proportionately more class D secretaries and low-wage establishments employed proportionately more class B secretaries.

In other instances, the published wage relationships may seem more reasonable, although they do not reflect those within single establishments. National wage data indicate that maintenance workers averaged almost twice as much in hourly pay as janitors and that men in office clerical occupations averaged more than their female counterparts. But, when intra-establishment averages are compared, these differences are smaller.

The analysis in this article is based on measures of occupational wage relationships—pay relatives—which reflect the pay practices and structures of employers. Pay relatives express earnings for an occupation as a percent of average earnings for a benchmark occupation in the same establishment. Janitor ("janitor, porter, cleaner") is used as the benchmark here because the job is widespread among establishments and is usually at or near the bottom of the wage scale—a convenience when analyzing pay relatives. The pay relatives were computed by dividing an establishment's average hourly earnings for the occupation being compared by the average for janitors.[3] The next step was to array the pay relatives for establishments contributing to an occupational comparison (one pay relative per establishment, weighted by establishment and area weights) and determine the median of the array. The results are presented in table 1.

Occupations were not compared one to another (for example, class A typists to class B typists). If they had been, the results discussed in this article might be quite different because the establishments included in the comparisons would have been different.[4] For example, establishments employing janitors and class A typists are not likely to be identical to those employing class A and class B typists.

Intra-establishment patterns

Nationwide. Based on median establishment pay relatives, blue-collar occupations averaged more than the janitorial occupation; a number of white-collar occupations averaged less. (See table 1.) Top-level secretaries were the highest paid clerical workers in 1976, averag-

ing 45 percent more than janitors. Messengers and entry-level file clerks were the lowest paid, averaging 14 percent less than janitors. Seven of the 26 office clerical occupations had pay relatives below 100.

Pay relatives for the 17 professional and technical occupations varied with the duties and responsibilities. Drafter-tracers who prepare simple drawings or copy drawings by tracing had the lowest pay relative of the group; systems analysts responsible for the most complex problems had the highest in the entire study.

Unlike the professional and technical group, pay relatives for 11 of the 14 maintenance, toolroom, and powerplant occupations studied were clustered within a comparatively narrow band—128 to 143. These 11 specialized occupations generally are found in large unionized establishments and require a formal apprenticeship or equivalent training and experience. Pay relatives for tool and die makers were the highest and those for maintenance trades helpers and boiler tenders were the lowest. Pay relatives for material movement and custodial occupations (other than janitor) ranged from a low of 102 for watchmen to 123 for trailer truckdrivers.

Industry. Pay relatives based on janitorial pay were generally larger in nonmanufacturing than in manufacturing industries. For example, class A typists in nonmanufacturing earned 8 percent more than janitors, while their counterparts in manufacturing earned 7 percent less.

Among the nonmanufacturing industries, services held the most favorable pay position for office clerical workers with pay relatives averaging 5 points above those in all nonmanufacturing industries; wholesale trade was lowest, averaging 9 points below nonmanufacturing. Computer occupations' pay relatives were about 35 points higher in retail trade, finance, and services than in public utilities and wholesale trade. The lower relatives were due to comparatively high wages for janitors, rather than low wages for computer personnel.[5]

Pay relatives for the skilled trades were also higher in nonmanufacturing. At least two elements contributed to this relationship. First, many large department stores pay skilled trades workers the local union rates for construction, even though the stores may not have a union contract covering any of their workers. (Union construction rates are usually much higher than rates for skilled trades in manufacturing or other nonmanufacturing industries.) Second, average earnings of janitors are much lower in nonmanufacturing than in manufacturing, where their wage rates are more frequently set by collective bargaining agreements.

Regional. Median establishment pay relatives in the Northeast and West closely approximated the national pattern for office, professional and technical, and skilled plant occupations. However, pay relatives in the South were as much as 43 percentage points higher than the nationwide figures and those in the North Central region were as much as 31 percentage points lower. The less-skilled plant occupations generally followed the national pattern in all regions.

The South has historically recorded higher pay relatives based on janitor pay than the other regions.[6] This pattern reflects the comparatively low wages of janitors—not higher pay for other occupations in the South (wage levels for almost all of the occupations studied were lowest in the South). Conversely, the low pay relatives in the North Central region reflect comparatively high wages for janitors. In fact, 16 of the 26 office clerical occupations had pay relatives below the janitorial base, compared with 8 below in the West, 7 in the Northeast, and 2 in the South.

One explanation for the opposite pattern of wage relationships between the South and North Central regions may be the degree of labor-management agreement coverage. Three-fourths of the plantworkers in the North Central region were covered by union agreements, compared with about two-fifths of those in the

South; and about a tenth of the officeworkers were covered in both regions. It appears that when janitors are paid under labor-management agreements, they have a more favorable wage relationship with blue- and white-collar workers within the same establishment. This analysis made no attempt to isolate the influence of unionization on regional pay levels from other factors that bear on wages. Differences in industrial composition of regions should be taken into account when examining reasons for differences in regional wage structures.

Inter- and intra-establishment differences

Inter-establishment and intra-establishment wage relationships for selected occupations are shown in table 2. Roughly two-fifths of the janitors in the study were employed by janitorial services—a relatively low-paying industry with few of the surveyed occupations. Consequently, data from these firms widened the inter-establishment wage differentials by decreasing the average for janitors (the benchmark job), while not affecting the other job averages. The intra-establishment wage differentials were not strongly affected, because of the few occupational comparisons that can be made within janitorial firms and the method used in computing differentials.

The data for tool and die makers illustrate, to some extent, the effect of janitorial services on the two types of measures. The inter-establishment relative of 195 for tool and die makers indicates they earned nearly twice as much as janitors; in contrast, when comparisons are made within establishments, the pay relative of 152 indicates only a 50-percent advantage. This situation is not unique. For 6 of the 21 occupations shown, the inter-establishment differential is more than twice as large as the intra-establishment differential.

Table 2. Inter- and intra-establishment wage relationships for selected occupations, 1976

[Janitorial pay = 100]

Occupation	Inter-establishment relationships	Intra-establishment relationships
Systems analysts, class A	263	229
Systems analysts, class B	227	190
Programmers, class A	214	190
Tool and die makers	195	152
Electricians	189	140
Mechanics (motor vehicles)	185	132
Programmers, class B	180	160
Mechanics (machinery)	177	134
Truckdrivers, (all sizes)	166	118
Computer operators, class A	162	139
Secretaries	136	124
Computer operators, class B	135	125
Shipping and receiving clerks	135	119
Material handling laborers	133	103
Stenographers, senior	124	109
Accounting clerks, class B	101	102
Bookkeeping—machine billers	96	106
Bookkeeping—machine operators, class B	95	108
Messengers	92	86
Typists, class B	91	90
File clerks, class C	79	86

Two occupational groups averaged more, or less, than janitors, depending upon the type of comparisons being made. Using inter-establishment averages, bookkeeping machine billers and class B bookkeeping machine operators averaged 5 percent less than janitors; using the intra-establishment averages, they averaged 6 to 8 percent more.

Changes in wage relationships

Most of the occupations included in this study were also covered in 1962 and 1967. These earlier studies focused on occupational data identified by sex and provided separate estimates for manufacturing and nonmanufacturing, but not for all industries combined. The following tabulation shows wage relationships from the three studies:[7]

	Average wage relationships		
	1962	*1967*	*1976*
Manufacturing:			
23 office clerical occupations (women)	103	102	98
13 maintenance, toolroom, and powerplant occupations (men)	136	136	131
13 material movement and custodial occupations (men)	112	113	110
Nonmanufacturing:			
23 office clerical occupations (women)	113	111	108
10 maintenance, toolroom, and powerplant occupations (men)	150	149	148
10 material movement and custodial occupations (men)	122	122	118

Wage differences between male janitors and other occupational groups remained relatively stable from 1962 to 1967; since then, some wage compression has occurred. Several factors provide for some speculation as to the difference in patterns between the two periods. For example, wages, as measured by the Bureau's Average Hourly Earnings Index,[8] advanced less than 4 percent a year from 1962 to 1967, but about 7 percent a year from 1967 to 1976. Therefore, equal-sized cents-per-hour adjustments within establishments (either general wage increases or cost-of-living escalators) had more opportunity to cause compression during the latter period. Additional factors include the increase in the Federal minimum wage from $1.25 an hour prior to 1967 to $2.30 an hour in 1976, and the exemption of lower paid workers from the wage controls of the early 1970's. □

FOOTNOTES

[1] Data in the 1976 study relate to 262 Standard Metropolitan Statistical Areas of the United States (excluding Alaska and Hawaii), as

defined by the U.S. Office of Management and Budget through February 1974. BLS surveys are conducted annually in a sample of 70 areas selected to represent all of these areas. Establishments employing 50 workers or more are surveyed in six broad industry divisions: manufacturing; transportation, communication and other public utilities; wholesale trade; retail trade; finance, insurance and real estate; and selected services. See *Area Wage Surveys, Metropolitan Areas, United States and Regional Summaries, 1976,* Bulletin 1900-82 (Bureau of Labor Statistics, 1979).

[2] See *Area Wage Survey, South Bend, Indiana, Metropolitan Area, March 1976,* Bulletin 1900-5 (Bureau of Labor Statistics, 1976), p. 3.

[3] The establishments used in these computations were limited to those with 100 workers or more, employing janitors, and reporting data for workers in at least one of the other occupations studied. Thus, the number of establishments involved varied somewhat by occupation. Because the survey data used in this analysis are limited to selected occupations, the more common approach of comparing occupational pay to the average for a broader group, such as all production workers or all office workers, was not possible.

[4] An occupational pay matrix which directly compares occupations with each other in an establishment was introduced into the *Area Wage Survey* bulletins in January 1979. For a discussion on pay matrix techniques see Mark S. Sieling, "Interpreting pay structures through matrix application," *Monthly Labor Review,* November 1979, pp. 41-45.

[5] A table presenting additional data for nonmanufacturing industries will be presented in the forthcoming *Area Wage Surveys, Metropolitan Areas, United States and Regional Summaries, 1977,* Bulletin 1950-77 (Bureau of Labor Statistics, 1980).

[6] See "Occupational Wage Relationships in Metropolitan Areas, 1961-62," *Monthly Labor Review,* December 1963, p. 1426 and "Occupational Wage Relationships in Metropolitan Areas," *Monthly Labor Review,* December 1968, p. 29.

[7] A wage relationship was computed between male janitors and individual occupations within each establishment. The median of these wage relationships for each occupation was determined, and then averaged by occupational group. The average wage for male janitors equals 100. Data were not combined for men and women in the two earlier studies.

The sharp rise in wages of black women

Twenty years ago the average black woman employed full time was earning approximately half the wage rate of a similarly employed white woman. By 1975 almost complete racial parity in female wages had been achieved. Although this remarkable advance in the economic status of black women has accelerated in the last few years, it has received little serious analytical attention. In contrast, the significant but smaller income gains of black males during the 1960's generated considerable research attempting to disentangle possible sources of this improvement. Real wage changes of the magnitude observed for black females are so rare that it seems unlikely conventional explanations will suffice.

The paper and plastic bag industry: two distinct productivity phases

During 1967–77, output per employee hour accelerated after a sluggish increase during 1954–66; the rise was associated with improved technology and rapid growth in output as consumer demand surged

HORST BRAND AND CLYDE HUFFSTUTLER

Productivity in the paper and plastic bag manufacturing industry rose at an average annual rate of 2.9 percent between 1954 and 1977—slightly exceeding the 2.7-percent rate for manufacturing as a whole for the same period.[1] (See table 1.) The long-term productivity rise resulted primarily from improved technologies, especially in plastic bag production. Comparatively high output rates were induced by expansion in consumer spending on soft goods, the chief market for bags, helping to maximize utilization of staff and equipment.

The long-term trend in the industry's labor productivity has been marked by two distinct phases. Between 1954 and 1967, gains in output per employee hour averaged 2.6 percent per year. From 1967 forward, the rate of gain accelerated, rising to 3.4 percent a year. (For total manufacturing, the comparable figures read 2.8 percent and 2.3 percent.) The acceleration was associated with intensified and widely diffused mechanization of work previously performed by hand. It was also indirectly linked with locational shifts of bag manufacturing plants closer to important market areas than to Southern paper mills. These shifts made reductions in job classifications under union contracts possible, which in the older plants still reflected dated manufacturing technologies.[2]

Year-to-year movements varied considerably. In 6 out of the 23 years examined, output per employee hour declined, as increases in employee hours exceeded increases in output. The years of decline were more than offset by the 10 years when productivity advances ran 50 percent or more above the long-term trend rate. Output gains then were accompanied by relatively small gains—and at times by losses—in employee hours.

Most of the years when output ran significantly above its own long-term trend rate were characterized by cyclical recoveries (for example, 1955, 1959, 1961, 1971, and 1976). The real value of consumer expenditures for soft goods rose strongly in such years. Moreover, output showed no year-to-year declines during the review period except for 1960, 1975, and 1977—also the only years when real consumer spending on soft goods rose weakly.

Output and demand: a long-term rise

The bag manufacturing industry converts paper into grocery bags and sacks, multiwall sacks, and specialty and wardrobe bags. It also converts plastic film into specialty bags, such as those that enclose much commercially sold presliced bread, or household bags used for sandwiches, refrigerator storage, or refuse. Furthermore, the industry manufactures the glassine (wax paper) or plastic liners that form the moisture and flavor barriers for foods packed in cartons (for example, dry

---

Horst Brand and Clyde Huffstutler are economists in the Division of Industry Productivity Studies, Bureau of Labor Statistics.

cereal); it also fabricates bags made of cellophane. The industry, which refers to the containers it makes as "flexible," is part of the group of industries manufacturing containers and packaging from various materials, accounting for approximately 11 percent by value of shipments.

Output of the paper and plastic bag manufacturing industry in 1977 ran 2½ times higher than in 1954—the first year for which adequate data for this study are available. The long-term output rise—4.7 percent per year between 1954 and 1977—considerably exceeded that for real consumer expenditures on soft goods for the period (2.8 percent). It also outpaced the expansion of such major user industries as commerical bread and bun bakeries (1.2 percent); for 1958–76, retail food stores (2.3 percent) and eating and drinking places (3.2 percent).

Among reasons for the comparatively rapid growth of bag manufacturing output has been the growth of supermarkets and the associated spread in unitized packaging of merchandise prior to display on retailers' shelves. This has meant that, in effect, given items are packaged twice—in the sealed bag (or other container) in which they are first enclosed for protection, and in the bag (or wrap) in which they leave the store. The unitizing of packages and the use of their surface as an advertising medium has been a tendency since about 1900. The advantages of pre-unitizing of packages by the manufacturer of the item packaged have been enhanced by steady improvements in packaging machinery since World War II, and their integration in the manufacturing process.[3] During the period reviewed here, unitizing prior to shelf display was spurred by the spread of self-service in supermarkets, convenience stores, hardware stores, and department and variety stores. Self-service usually requires that the prepackaged item be easily accessible, and that the package feature descriptive information and graphics.

Table 1. Productivity and related indexes for the paper and plastic bag industry, 1954–77

[1967=100]

Year	Output per employee-hour			Output	Employee-hours		
	All employees	Production workers	Nonproduction workers		All employees	Production workers	Nonproduction workers
1954	73.0	70.5	86.2	52.4	71.8	74.3	60.8
1955	76.5	74.0	90.0	57.3	74.9	77.4	63.7
1956	73.5	72.1	80.1	58.1	79.1	80.6	72.5

1977	130.2	132.1	122.3	133.8	102.8	101.3	109.4
	Average annual rates of change (in percent)						
1954–77 .	2.9	3.0	2.3	4.7	1.7	1.8	2.3
1973–77 .	1.0	1.4	–.5	–.0	–1.0	–1.4	.5

The industry's output of specialty bags and liners—which now consist preponderantly of plastic film[4]—more than quadrupled between 1954 and 1977; they accounted for more than half of total bag production in 1977, compared with one-third of a much smaller total in 1954. Advances in the sealing speed, seal integrity, and imprintability of plastic film greatly contributed to the rapid growth in their use—exemplified by the bread baking industry's switch from wax paper wraps to plastic bags or wraps in the mid-1960's.

Output of grocery bags and sacks, the mainstay of the paper bag production segment of the industry, nearly doubled over the period reviewed, with its share of total industry output, close to one-quarter in 1977, changing little. The demand for commercial-type bags and glassine, as well as for plastic bags, has been spurred by expanding carryout sales at restaurants accounting for 15 percent of their total sales in 1972.

Output of multiwall bags and shipping sacks rose by 40 percent over the period but dropped in relative importance, from two-fifths of the industry's total production in 1954 to about one-quarter in 1977. Gains in demand have been slowed by a shift in shipping methods—from bags to bulk. For example, according to Census and Bureau of Mines data, establishments manufacturing phosphate fertilizers reduced their consumption of multiwall bags by close to one-fifth between 1963 and 1972. Portland cement plants shipped 21 percent of their product in bags in 1958, but only 8 percent in 1975.

Employment pattern by phases. Employment in the bag manufacturing industry, currently at 53,000 persons, rose at an average annual rate of 1.8 percent between 1954 and 1977; hours at the plant rose by nearly the same long-term rate (1.7 percent). The trend, however, is distinguished by two phases. Until 1967, employment increased an average of 2.4 percent a year, but from then on, less than 1 percent. Hours at the plant rose in tandem with employment during the former period, but, like employment, they remained virtually unchanged during the latter. This reflected an exceptionally sharp cutback in hours (nearly 11 percent) in 1975. In 1977, employment stood 43 percent above 1954 levels, but ran significantly below the high it had reached for the period as a whole in 1970—when it had moved to 60 percent above 1954 totals.

Nonproduction workers grew in relative importance over the 23-year period. The average annual rate of increase in their number, 2.4 percent, was significantly higher than that for production workers, 1.6 percent. Currently, production workers account for 78 percent of total industry employment (compared with 71 percent for manufacturing as a whole). In 1954, their share was 83 percent. This rise in the proportion of nonproduction workers has in part been due to expanded professional staff, because with the shift to plastic film, research and testing personnel were increased by the larger firms. Also, computer-run extruders have required technical personnel over and above the normal complement of engineers and quality control teams needed in the plants.

Technological developments

The making of paper bags and of plastic bags differs in important respects. The basic material for plastic bags, that is, plastic film (usually polyethylene) is extruded from pelleted resins on the premises of the larger bag manufacturing plants. In contrast, the stock for paper bags is delivered from paper mills (classified in the paper and pulp industry). Improvements in extrusion technology have been a significant factor of productivity change in bag manufacturing. Improvements in the making of the paper stock for bags, however, are not reflected in the productivity measure discussed here.

The paper or plastic film roll is first imprinted according to customer specifications. The paper roll is fed into the bag-making machine, where generally, it is preperforated, tubed, cut, bottomed, and glued. For multiwall bags, the tubing and bottoming processes are usually separate. Plastic bags are cut from rolls; they are sealed by heating as they are cut. Paper bags are stacked and bundled for shipment at the end of the manufacturing process; plastic bags may be "wicketed," that is hung upon pins, ready for machine-filling by the customer. They are then crated or cartoned for shipment.

Technological advances in all parts of the bag-making process have contributed to rising output speeds, and hence declines in unit labor requirements. Over the past 10 to 15 years, the number of standard grocery bags produced by up-to-date equipment has roughly doubled per shift. One factor here has been the installation of so-called single-size bag-making machines in place of multisize machines.[5] Furthermore, the completed bags are mechanically indexed (that is, counted), stacked, and bundled—operations previously performed manually.

Production of multiwall paper bags and sacks remains somewhat more labor-intensive. Runs are more limited than for standard bags, because they are determined by customer specifications regarding size, thickness, type of bottoms, and type of closure. For some uses, the sewing of the bag's filling end is specified. Multiwall bags, then, are produced for inventory to only a limited extent, and machines must be reset after each run. Nevertheless, machinery operates at speeds estimated to be about one-fifth higher than a decade ago.[6] Innovations have been modest but steady; for example, gears are now bathed in oil; tubers and bottomers are mechanically connected, so labor for the transfer has been eliminated. Sewing apparatus is fed automatically rather than manually as in the past.

Product changes

Certain changes in the product have helped boost production speeds. For example, self-closing valves have replaced a variety of closure systems, including sewing. Such product changes have partly resulted from advances in filling equipment, requiring high-speed closing of bags.[7]

Some striking technological advances characterized the manufacture of plastic bags during the period studied. Machinery used today can produce up to 250 polyethylene bags per minute, roughly 4 times more than 2 decades ago.[8] One reason for the higher speeds has been more rapid rates of sealing (or "welding") of the bag's bottom. Also, the wicketing of bags has been automated (although in some installations, manual labor is still used), and this automation has raised hourly output by as much as 60 percent.[9]

To attain high production speeds for plastic bags, difficult problems other than the forming of the bag from film have had to be tackled. These problems tend to retard the output capacity of advanced equipment. Some larger companies maintain substantial research facilities to deal with such matters, as the printability of plastic films; less labor-intensive printing machinery; drying speeds of ink; adhesion of liners; and seal integrity.

As mentioned, the larger plastic bag plants often extrude their own film from resin pellets. Extrusion in its most advanced form is a completely automated process. The pellets are melted electrically and, in the case of the so-called cast extrusion process, which produces single-layer sheets, by the friction of the extruder screw. The efficiency of the screw has come to be maximized by means of screw designs derived from experience and embodied in computer programs for screw geometry.[10] The melted plastic is forced out through a slot die onto a chill drum, where it forms into a sheet. The sheet's thickness is computer-scanned and -controlled. The speed at which the rolls of plastic sheet become available to the manufacturing processes depends in good part on the chill drum's heat absorption characteristics, which remain a subject of concern to production engineers.[11]

Blown film extrusion, applied in the manufacture of double-sheeted film for refuse bags and related consumer uses, has also progressed technologically, particularly in efficiently cooling the extruded film without interfering with its speedy transfer to flattening rollers and perforating and cutting processes. Futhermore, the combining of different polymers offering various properties in the final plastic film—for example, toughness, moisture barrier, oxygen barrier—has spelled material economies, and has also accelerated manufacturing processes.[12]

The plastic sheet, prior to being imprinted, is treated by corona discharge so as to disturb its surface electronically and render it imprintable. Paper used for bags and sacks does not require pre-print treatment. The absorbability of paper permits the use of water-based inks, while plastic film requires more volatile, solvent inks. Heat to speed drying is nonetheless applied, but to cut associated energy costs, research to dispense with heating is underway.[13] Innovations in printing machinery, particularly in press speeds, and inking and drying systems, have helped accelerate both paper and plastic bag manufacturing processes. Printing units have been produced in recent years that permit removal of components (for example, the printing trolley) without tools. Component removal facilitates preparation for the next job, as well as cleanup and maintenance. Loading and unloading at the wind and rewind end of the press have been automated.[14]

The use of cellophane for bags and wraps has been declining, and it is being replaced by plastic film (chiefly polypropylene). Cellophane's machinability (determined by a material's relative stiffness) and imprintability compare well with plastic film, but plastic film features comparable characteristics in preserving flavor and barring moisture. Plastic film has the advantage of being cheaper than cellophane, and more energy-efficient in production.[15] The impact of the shift on unit labor requirements has probably been favorable, as the older cellophane-producing equipment has been phased out and advanced plastic film- and bag-producing equipment has replaced it.

During 1954–76 capital expenditures in the bag manufacturing industry quadrupled, doubling during 1967–76. The increase ran closely in line with that for manufacturing as a whole. Capital expenditures per employee, however, generally tended to lag the manufacturing average. In 1976, for example, the industry averaged $1,900 per employee on plant and equipment, or 81 percent of the $2,300-per-employee average for manufacturing as a whole. Moreover, the ratio declined somewhat from the early 1960's. The decline reflected the lessening importance of new (or expanded) plant construction by bag manufacturers, compared with factory building in general. The industry rents a comparatively high proportion of its plant space—the equivalent of 75 percent of its spending on structures in 1975, as against 43 percent for all manufacturers. Moreover, investment in new machinery and equipment has accounted for a higher proportion of bag manufacturers' total capital outlays than of all manufacturers'. And machinery and equipment outlays per employee in the industry were not less than 90 percent of the manufacturing average between 1958 and 1975, and came close to, or exceeded it in 1972 and 1963.

Of the 583 establishments classified in the industry by the Census of Manufactures for 1972, less than a quarter accounted for more than 70 percent of capital expenditures, employment, and value of shipments. More than three-quarters of all establishments had fewer than 100 employees; 43 percent had fewer than 20, accounting for but 4 percent of total industry employment and value of shipments.[16]

Industry outlook

Continued gains in the labor productivity of the bag manufacturing industry are likely, although perhaps at somewhat lower rates than in the past 10 to 12 years. To a degree, the gains will be linked to continued high rates of output. While opportunities for packaging new or existing products have for some time been fully exploited, partial shifts away from such materials for containers and packaging as metal (for metal cans); glass (for glass containers); and paper (for paper cartons), and to plastic film or plastic film constructions, are likely to spur plastic bag manufacturing. Thus, for example, retort pouches, constructed usually of film and foil, are expected to make gradual inroads into the use of metal cans used to market canned foods. Frozen foods, currently packed mostly in paper cartons, may also, in part, be replaced by foods sold in pouches. For the present, the spread of pouches for food packaging is impeded by consumer reluctance to accept them, and by slow filling speeds.[17]

Machinery design improvements to attain higher output speeds will continue to be at a premium. It is expected, for example, that high productivity chill rolls on extruders will accelerate heat transfer, thus making for stepped-up production of cast-extruded film. Analogous developments are anticipated for blown film extrusion.[18] Printing is likely to become less labor intensive as innovations in gravure and letterpress printing, as well as in inking systems, already well diffused in the printing and publishing industry, are more widely applied in bag manufacturing.[19] In regard to paper bag manufacturing, it seems likely that improved tear strength in the materials used, and elimination of flaws, will continue to reduce downtime. ☐

FOOTNOTES

[1] The industry consists of establishments primarily engaged in manufacturing bags (other than textile bags) from purchased paper, cellophane, acetate, polyethylene, polypropylene, pliofilm, foil, and similar sheet and foil materials. It is designated as No. 2643 in the Office of Management and Budget's *Standard Industrial Classification Manual*, 1972.

The average annual rates shown in the article and table are based on the linear least square trend of the logarithms of the index numbers. Extension of the indexes for future years will appear in the annual BLS publication, *Productivity Indexes for Selected Industries*.

APPENDIX: Measurement techniques and limitations

The productivity indexes in this study measure the change over time in industry output per unit of labor input. They do not measure the specific contribution of labor, but reflect the influence of many factors such as technology, capital investment, and managerial skills, as well as the skill and effort of the work force.

The output index is based on value of shipments data, published by the Bureau of the Census. Detailed data from the Census of Manufactures for 1954, 1958, 1963, 1967, and 1972 were used to derive benchmark indexes, to which the annual indexes for intervening years, based on the Annual Survey of Manufactures, were adjusted. The value of shipments of the various product classes was adjusted for price changes by appropriate Producer Price Indexes to derive a real output measure. In turn, the product classes were combined with employee-hour weights to derive the overall output measure. Employment and employee-hour indexes were derived from Bureau of the Census data. The number of employees and employee-hours is considered homogeneous and additive, and the pertinent measures thus do not reflect changes in the qualitative aspects of labor.

Does the CPI exaggerate or understate inflation?

DANIEL J. B. MITCHELL

During periods of rapid inflation, the Consumer Price Index (CPI) is closely scrutinized by press and public. There is a natural tendency—when news is bad—to blame the messenger. In particular, it is often charged that the CPI is inherently upwardly biased[1] and that, therefore, it overstates the impact of inflation in reducing real earnings. It is only a small step from that charge to the conclusion that the CPI itself is inflationary because of its effect on indexed wages and incomes and on the perception of inflation by nonindexed groups.[2]

When the CPI is criticized for overstating the rate of inflation, two problems are most often mentioned. First, it is noted that the CPI has fixed weights and, thus, does not account for substitution effects induced by changes in relative prices. Second, it is said that the CPI cannot adequately reflect quality improvements, innovations, and new products. Such problems are inherent in index numbers, but there is no reason to assume that other elements in the construction of the CPI do not offset these biases. A third complaint during the recent period concerns the treatment of the housing sector. Basically, house purchases are treated in the same manner as other durable goods purchases in defining the CPI. Because house prices have increased substantially relative to other prices, it might be assumed that the inclusion of house prices had a substantial impact in pushing up the overall index.[3]

Is it true that the CPI has only upward biases? Or are there measurement and conceptual elements of the index which push in the other direction? Critics of the CPI have concentrated on the upward biases and have ignored important counteracting effects. The house-price component of the CPI appears not to have reflected as much inflation during 1968–78 as other indexes of house prices. And the new car component—due to "quality" adjustments—has not reflected the full increase in "expenditures per car" experienced by consumers. In December 1978, the home-purchase weight in the CPI for all urban consumers was slightly more than 10 percent (9 percent for urban wage earners and clerical workers) and the new car weight was just under 4 percent. Thus, difficulties in measuring these components can have a noticeable effect on reported inflation rates.

House prices

Although the rapid increase in house prices was one of the most discussed economic phenomena of the 1970's, the CPI home-purchase component reported an annual increase of only 6.7 percent a year during 1968–78. During the same period, the All-Items CPI rose at a 6.5-percent rate.[4] Thus, while the CPI did report some relative price increases in homes, the gain of 0.2 percent a year is hardly remarkable and its moderate size would surprise many home owners and buyers. Other indexes of house prices show a more rapid annual rate of inflation, as shown in the following tabulation:[5]

Bureau of the Census new-house price index (quality adjusted)	8.5
National Association of Realtors existing-house price index (not quality adjusted)	9.5
FHA:	
New home acquisition costs	7.6
Existing home acquisition costs	7.5

The CPI home-purchase component is based on data collected from the Federal Housing Administration (FHA), which insures mortgages primarily of lower priced housing. Unfortunately, dollar ceilings on mortgages the FHA will insure tend to inhibit price increases observed from FHA data. The number of new FHA-insured mortgages varies from year to year, but generally declined during 1968–78. The fact that unadjusted indexes of acquisition costs of FHA-insured houses[6] rose faster than the CPI's home-purchase component may be due to quality adjustments included in the CPI figure. But, if so, the quality adjustment is greater than that made by the Census Bureau in its new-house index.[7]

Daniel J. B. Mitchell is director of the Institute of Industrial Relations, University of California, Los Angeles, and professor at the Graduate School of Management. Some of the results reported in this note were developed when the author was a senior fellow of the Brookings Institution. However, the views expressed do not necessarily reflect those of Brookings, its trustees, or staff.

In summary, the CPI home-purchase component rose more slowly than other indexes of house prices. Because the home-purchase component did not rise much faster than the all-items index, it did not have a strong influence in pulling up the measured rate of inflation during 1968–78. In fact, other measures of house prices would have pushed up the CPI faster.

Car prices

The new-cars component of the CPI increased at a 4.5-percent annual rate during 1968–78, significantly slower than the all-items index (6.5 percent). Buyers of new cars, however, may find this reported relative decline at variance with their personal experience. The National Automobile Dealers Association's index of expenditures per new car showed a 7.2-percent annual gain.[8] The used-cars component of the CPI rose 6.6 percent a year, higher than the all-items average. Because used cars are presumably substitutes for new cars, the substantial divergence in inflation rates for new and used cars is initially surprising.

The gap between the CPI index for new cars and the National Automobile Dealers Association's index of expenditures per new car is largely explained by various "quality" adjustments applied to new car prices before the CPI component is calculated. Much of the adjustment is due to the addition of mandatory safety and pollution equipment. The fact that such devices had to be required by law suggests that consumers value the devices at less than their actual cost.[9] There is also a question as to whether the "downsizing" of new cars to meet fuel economy standards should be considered a quality deterioration, although it was not so treated in computing the CPI new-cars component. Obviously, if mandatory equipment had not been treated as a quality improvement and downsizing had been treated as a quality deterioration, the new-cars component of the CPI would have risen faster than the 4.5-percent reported during 1968–78.

Alternative procedures

The following tabulation shows the possible effect on the measured rate of inflation during 1968–78 if the CPI had been computed differently:

	Annual increase
CPI, all items (actual)	6.5
CPI, all items, substituting:	
Expenditures per car index (for CPI's new-cars component)	6.6
New-and existing-house price indexes (for CPI's home-purchase component)	6.8
Combination of the two alternative indexes	6.9

If the National Automobile Dealers Association's expenditures per car index had been substituted for the new-cars component, the all-items index would have risen about 0.1 percent faster per year. If the Bureau of the Census' index of new house prices and the National Association of Realtors' index of existing house prices were substituted for the home-purchase component, the all-items index would have risen about 0.3 percent faster per year.[10] The combination of the two alternative indexes for new cars and houses would have raised the all-items index by 0.4 percent a year.

IT IS EVIDENT that not all the biases in the CPI push the index upward. Some elements of measurement and methodology have had the opposite effect. Although there is no guarantee that the errors and biases of CPI methodology will cancel out exactly, critics should avoid concentrating only on particular problems of measurement or concept in evaluating the overall CPI as a measure of inflation. ☐

FOOTNOTES

[1] For example, see "U.S. Inflation Index is Inflationary, Critics Contend," *Los Angeles Times*, Dec. 27, 1979, Part III, pp. 12, 21.

[2] It has been estimated that 50 percent of the U.S. population receives some indexed income, although only 15 percent of total income is indexed. See Julius Shiskin, "A new role for economic indicators," *Monthly Labor Review*, November 1977, pp. 3–5.

[3] This note does not address the issue of whether housing consumption should be treated as it is under current CPI methodology or whether—as some critics have suggested—as a flow. See Lawrence E. DeMilner, "Statement before the U.S. House Budget Committee Task Force on Inflation," Dec. 14, 1979, for arguments in favor of a flow concept.

[4] This statement refers to the CPI for urban wage earners and clerical workers which was available throughout the period.

[5] The quality-adjusted index for new houses are from *Price Index of New One-Family Houses Sold, Fourth Quarter 1978* (Bureau of the Census, 1979), p. 3. This index is based on a standarized house sold in 1978 and is adjusted for 10 important characteristics. The existing-house price index is from *Existing Home Sales* (National Association of Realtors, April 1979), p. 10.

[6] Data on FHA-insured mortgages are from the *1975 Statistical Yearbook* (U.S. Department of Housing and Urban Development, 1978), tables 41–42; and from data supplied by HUD to the author.

[7] The quality adjustment applied to the Census Bureau's new-house price index subtracts only about 0.3 percentage points a year from the unadjusted rate of new house inflation during 1968–78.

[8] Data on expenditures per new car are from *NADA Data for 1979* (National Automobile Dealers Association, 1979), p. 5; or were supplied to the author by the association.

[9] Some quality improvements stemmed from features which were not legally mandated. For example, options such as power brakes, power windows, and air conditioning have become more common in recent years. See *Statistical Abstract of the United States, 1979* (Bureau of the Census, 1979), p. 649. Concerning mandated equipment, however, there is an inconsistency in current methodology. The costs of safety and anti-pollution equipment used in the factories producing new cars are presumably reflected in car prices. Yet, no quality adjustment is made for such devices. Thus, an anti-pollution device on the factory smokestack is not viewed as an improvement in the quality of cars produced in the factory. But a similar device on the car's tailpipe is considered a quality improvement.

[10] The alternative house-price component was computed as a weighted average of the Census Bureau's new-house price index and the National Association of Realtors' existing-house price index. The weights on new and existing houses were 29 percent and 71 percent, respectively. These were the proportions of new and existing house sales during 1972-73, the same period used in the most recent weighting of the CPI. Data on existing house sales are from *Existing Home Sales* (National Association of Realtors, April 1979), p. 4. Data on new home sales are from *New One-Family Houses Sold and For Sale* (Bureau of the Census, November 1977 and February 1979), table 1. To compute the effect of substituting the alternative indexes in the CPI, an approximation was used. The CPI weights (all urban consumers) for December 1978 were projected to earlier years by taking account of price inflation in the various components of the index. These weights will not be identical to those actually used to calculate the CPI, but will give reasonable approximations.

Does the CPI exaggerate or understate inflation? Some observations

JACK E. TRIPLETT

Daniel Mitchell's paper provides a timely reminder that measurement errors in price indexes do not always result in overstatement of inflation. This point seems to have been overlooked in much recent public discussion of the Consumer Price Index.

Many critics of the CPI cite unmeasured quality change as a reason for assuming that the index overstates inflation.[1] However, research findings on this subject are not entirely consistent with what many of the CPI's critics seem to believe. Some studies of quality change in price indexes have pointed to possible downward errors in certain components of the indexes (including autos, rental housing, and some appliances); for other components, researchers obtained the opposite result.[2]

When a researcher produces a price index that differs from one published by the BLS, that does not necessarily mean the BLS index is wrong. Examining alternative data sources, computational methods, ways of handling quality change, and so forth can be very useful in the continuing and ongoing process of evaluation that a statistical agency must pursue to assure that its output is of the highest quality possible. But when these alternative procedures give results different from those currently in use in the CPI (or in some other price index), the evaluation has just begun. We must test the plausibility of the alternative indexes against other known facts, and against knowledge of the actual problems that arise in price index construction. Only when the alternative indexes "fit in" with other information can we have confidence that the messages they give are not misleading.

House-price indexes

Mitchell points out that other measures of home prices, particularly the Census Bureau's index of the prices of new homes, have risen faster than the CPI home-purchase index. The discrepancy between the Census and CPI series has widened as the pace of inflation in home prices has accelerated over the past 3 years, so that the discrepancy is considerably larger for recent years. The following shows percent changes in the CPI's home-purchase component and the Bureau of the Census new-house prices index:

	CPI home purchase	*Census new home price*	*Difference*
1973-74	7.5	9.4	-1.9
1974-75	12.3	10.0	2.3
1975-76	5.1	8.4	-3.3
1976-77	6.6	12.3	-5.7
1977-78	9.6	14.1	-4.5
1978-79	13.4	13.8	-.4

The Census index is computed exclusively from prices of newly constructed homes; the BLS home-purchase index includes both new and existing homes. However, in most parts of the country there seems little reason to suppose that the upward trend of prices of previously occupied homes has not kept up with prices of new homes. What, then, can account for the difference between the two indexes?

The two indexes differ in data bases, computational methods, and in the way they handle quality change. Data for the Census index come primarily from builders. The CPI home-purchase index is compiled from data on home sales which involve mortgages insured by the Federal Housing Administration or the Veterans Administration. This is the only available data base which meets CPI needs for a national index, and also for 28 city indexes and 16 city size and regional indexes. The data base does, however, have known problems.

The Census index is computed by hedonic methods[3] which hold constant a set of 10 characteristics of houses, such as floor space, number of bathrooms, locational factors, and so forth. The BLS index holds a somewhat smaller set of factors constant, including size, age, and geographic area. Both indexes are subject to potential quality error for changes in characteristics which are not held constant in the procedures used in their construction.

Little information about the statistical properties of the Census index and its data base is currently available. John Greenlees, in an as yet uncompleted BLS study, has shown that quality change in the FHA-VA sample creates a *downward* bias in some of the city home-purchase indexes that make up the CPI.[4] It is not

---

Jack E. Triplett is Assistant Commissioner, Office of Research and Evaluation, Bureau of Labor Statistics.

best copy available

yet certain whether this result will hold for all CPI city indexes, but Greenlees' preliminary finding provides insight for interpreting the CPI-Census house price comparisons. If we have reason to suspect a downward quality error in the CPI home-purchase index, it is indeed reasonable to look to an independent index of new-house prices for suggestions about the probable magnitude of the problem.

The more rapid the inflation rate of homes, the more rapidly do those prices "bump" against the FHA–VA ceiling—thus, one might expect the problem with the CPI data base to be more severe in rapid inflation (and, conversely, to be rather more manageable at lower inflation rates). Mitchell's comparison of home-price indexes thus gives results that seem plausible. Though it is too early to tell why the two indexes give similar results for 1979 (both showing a nearly record rate of inflation for home prices), when the FHA–VA ceiling is raised, it tends to diminish the quality error in the BLS series.

Rental-cost index

At least two research studies of rental price indexes have suggested similar downward-bias problems. It has long been known that the CPI rent measure has an inherent "aging bias" because of unmeasured month-to-month deterioration.

In 1972, Rafael Rom Weston[5] compared the CPI rent index with an index based on decennial Census data, which he adjusted for depreciation. For the 1960–70 interval, his quality-adjusted Census index (31.4 percent) rose about 50 percent more than the CPI rent index (20.0 percent). More recently, James Follain and Stephen Malpezzi of the Urban Institute computed a quality-adjusted index from the Annual Housing Survey for the years 1974–76. This, too, showed greater rates of increase than the CPI rent index:[6]

	CPI rent index	*Urban Institute rent index*
1974–75	5.5	5.9
1975–76	5.3	6.9
1974–76	11.1	13.2

Many economists have substituted the CPI rent index for the published CPI homeownership component, a recomputation that results in a lower overall index. Alternatively, others have preferred the Commerce Department's Implicit Price Deflator for Personal Consumption Expenditures (PCE) on the same grounds: the PCE uses the CPI rent index as a proxy for the cost of homeownership. However, because of aging bias in the rent index, such indexes probably understate inflation. This conclusion also applies to Experimental Index X-1 now published monthly by the BLS.[7]

Car-price index

Mitchell's discussion of automobile prices is less persuasive. The CPI new-cars index is adjusted for quality change using information from manufacturers, but comparable quality adjustments are not applied to the used-cars index, which suffers also from an inadequate data base. And an "expenditures per new car" series will clearly rise when quality improvements are incorporated into new cars, while a valid price index would not. Thus, both alternative series probably have more severe quality errors than does the CPI new-cars component. Yet, his statement that "if mandatory equipment had not been treated as a quality improvement . . . the new-car component of the CPI would have risen faster . . ." is certainly correct. And a number of previous studies of the CPI new automobiles index suggest that measurement error, when it exists under present procedures, might cause the index to rise somewhat too slowly—though differences between research indexes and the CPI are small, and the research indexes are also subject to certain biases.[8]

Mitchell's general point is correct: "Critics of the CPI have concentrated on the upward biases . . ." In the process, they have overlooked evidence of bias in the other direction. Price index measurement is, like all forms of measurement, subject to error. No one really knows the net effect of offsetting upward and downward quality errors in index components on the overall CPI. Mitchell's paper fits in with a wide body of research which, taken together, tells us we should not assume that improving the measurement will necessarily lower the measured rate of inflation. □

FOOTNOTES

[1] Mitchell also mentions another problem—that a fixed-weight price index formula suffers from a "substitution bias" because it makes no allowance for changes in consumption in response to relative price changes. An article covering recent research on the substitution bias question is in preparation and will appear in a future issue of the *Monthly Labor Review.*

[2] A survey of published studies on quality error in price indexes is contained in Jack E. Triplett, "The Measurement of Inflation: A Survey of Research on the Accuracy of Price Indexes," in Paul H. Earl, ed., *Analysis of Inflation* (Lexington, Mass., Lexington Books, 1975).

[3] This is a regression procedure for holding quality change constant in the sample from which the price index is computed or (alternatively) for deriving adjustments for quality change that can be used within the framework of traditional price index formulas. A standard reference is in Zvi Griliches, ed., *Price Indexes and Quality Change: Studies in New Methods of Measurement* (Cambridge, Mass., Harvard University Press, 1971). See also Jack E. Triplett, *The Theory of Hedonic Quality Measurement and Its Use in Price Indexes,* Staff Paper 6, (Bureau of Labor Statistics, 1971).

[4] The demonstration of this is in Greenlees' forthcoming paper. Briefly, the more expensive and higher quality houses qualifying for FHA–VA mortgages in one period will not qualify for them later because of housing inflation. This creates a slow monthly deterioration in average quality in the sample, which can cumulate over time to yield an index which rises more slowly than the true rate of inflation

in home prices.

Hogarty, "Price-Quality Relations for Automobiles: A New Approach," *Applied Economics*, Vol. 7, 1975, pp. 41–51; and Makota Ohta and Zvi Griliches, "Automobile Prices Revisited: Extensions of the Hedonic Hypothesis," in Nester E. Terleckyj, ed., *Household Production and Consumption*, Studies in Income and Wealth, Vol. 40, National Bureau of Economic Research (New York, Columbia University Press, 1975), pp. 325–90.

Measures to cut costs and prices

What effect can we expect on the ongoing inflation rate from one-time increases or reductions in prices or costs? We can rely on cost changes to be reflected in prices. Beyond that, the empirical evidence is unfailingly ambiguous. The price shocks of the mid-1970's affected wages, but not proportionately. Consumer prices appear to have some persistent effect on wages, but it is modest once the effects of lagged wages themselves are allowed for. On the basis of the evidence, it appears that only a minor fraction of any shock to prices would filter through into average wage changes and thus have some multiplied effect. That still makes measures to cut prices and costs worth pursuing and their opposites worth avoiding. Even if only one-quarter of any price change influences wages, 1 percent removed from the CPI reduces wage inflation by about as much as 1 percentage point more unemployment for 1 year.

—GEORGE L. PERRY

"Slowing the Wage-Price Spiral: The Macroeconomic View," in Arthur M. Okun and George L. Perry, eds., *Curing Chronic Inflation* (Washington, The Brookings Institution, 1978), p. 55.

Special Labor Force Reports—Summaries

Women's share of moonlighting nearly doubles during 1969–79

EDWARD S. SEKSCENSKI

Nearly 1 in 20 workers held more than one job during the survey week in May 1979. Since May 1969, despite some fluctuations, the number of "moonlighters" has grown at about the same rate as the total work force; by May 1979, about 4.7 million persons held more than one job.[1] The most striking change in the moonlighting work force during the decade is the proportion of women in its ranks. About 3 of every 10 multiple jobholders in May 1979 were women, nearly double the proportion of 10 years earlier. (See table 1.)

Multiple jobholders are persons who were: wage or salary workers with more than one employer, self-employed but also held a wage and salary job, or unpaid family workers on their primary jobs but also held wage and salary jobs.[2] The primary job is the one where the greatest number of hours was worked.

Patterns by sex and race

In May 1969, about 658,000 women held more than one job, representing 16 percent of all moonlighters. By May 1979, moonlighting women numbered 1.4 million, accounting for 30 percent. However, the number of men with multiple jobs remained about 3.3 million. These changes are consistent with the increased proportion of women in the total work force, many of whom are the primary earners in their families.[3] Further, the growth in the number of multi-earner families may have diminished the economic incentive for some husbands to hold more than one job.

While the reported incidence of multiple jobholding has long been lower for black than for white workers, the difference has grown considerably in recent years. The moonlighting rate for black men has dropped more rapidly than that for white men. The rate for black women has remained largely stationary, while that for white women has risen sharply.

Between 1969 and 1979, the reported incidence of moonlighting among black men dropped from 6.1 to 3.8 percent, while the rate for white men declined from 7.0 to 6.1 percent. During the same period, the rate for black women edged down, from 2.2 to 2.0 percent, but the rate for white women increased from 2.3 to 3.7 percent. However, although black women were less likely than white women to hold more than one job, they were more likely to work full-time on at least one job.[4]

Industry and occupation

Groups of industries employing large proportions of workers who also moonlighted during May 1979 included public administration, 7.6 percent, and agriculture and services, 6.1 percent each. Within these groups, the specific industries with the highest proportions of moonlighters were State and local administration, 9.3 percent; education, 8.2 percent; and entertainment and recreation, 7.3 percent. (See tables 2 and 3.)

About 15 percent of second jobs were in agriculture, more than 4 times the percentage of primary jobs in the industry. One-third of multiple jobholders, including nearly two-fifths of the men, were self-employed in their second jobs. The proportion of moonlighters working their secondary jobs in services, 30 percent, was slightly higher than that for single jobholders.

Among the major occupational groups, farmers and farm managers, and professional and technical workers reported the highest rates of moonlighting. Nearly 1 in 4 multiple jobholders in May 1979 was a professional or technical worker, up from less than 1 in 5 in 1969. Women in these occupations accounted for more than 60 percent of the increase. Particularly large increases in moonlighting occurred among women teaching in primary and secondary schools, and persons working in health professions. The moonlighting rates for men in these two professions, though more than twice that of women in comparable jobs, were down by about one percentage point each, from their 1969 levels. Another occupational group with a high proportion of moonlighting men was protective services, such as police who also work as private guards. This rate, however, also decreased during the decade, from slightly less than 17 percent to about 12 percent.

Occupational groups with lower than average rates of multiple jobholding in May 1979, as well as 10 years earlier, included factory operatives and clerical workers.

Edward S. Sekscenski is an economist in the Office of Current Employment Analysis, Bureau of Labor Statistics.

Table 1. Persons holding two jobs or more and multiple jobholding rates, May 1969 to May 1979

[1] Multiple jobholders as a percent of all employed persons.

[2] Starting with 1977, data are for black workers only. Data for prior years are for persons of black and other races except white, about 90 percent of whom are black.

Although differences exist in the responses given by men and women, the distribution of reasons for working more than one job has shown few year-to-year changes since 1974, the first period for which comparable data are available.[5] About 29 percent of men and 34 percent of women stated "meeting regular expenses" was the main reason for holding two or more jobs during the survey week. (See table 4.) In 1974, 33 percent of men and 30 percent of women cited this as their main reason. However, among black women, about half of those with more than one job gave the need to meet regular expenses as their principal reason for moonlighting, both in 1974 and 1979.

A larger proportion of men than women in May 1979 said "saving for the future" was their main reason for holding more than one job. More older workers than young ones offered "enjoying the work" on their second jobs as the main reason. More younger workers said it was "paying off debts." The proportion of women working a second job "to get experience" increased in almost every age group during 1974–79.

Marital status, historically, has been a factor in the decision to moonlight. The highest rates were exhibited by married men, especially those with two children or

more. The lowest rates have been shown by married women. However, in the 1969–79 period, rates for married men declined and those for married women increased by about one percentage point each. The rate for widowed, divorced, and separated women rose from 3.5 to 4.3 percent. Single (never-married) women showed an even larger increase in moonlighting during the period, from 2.5 to 4.4 percent.

About two-thirds of multiple jobholders worked one full-time and one part-time job. More than three-fourths of such persons were men. Nearly half of women moonlighters held two part-time jobs. The proportion of men holding two full-time jobs in May 1979 was twice as high as for women:

Multiple jobholders	*Both sexes*	*Men*	*Women*
Total [in thousands]	4,724	3,317	1,407
Percent distribution	100	100	100
One full-time, one part-time job	67	75	51
Two part-time jobs	27	19	48
Two full-time jobs	5	7	3

An average total of 52 hours was worked by moonlighters during the survey week. Hours worked on secondary jobs averaged 13; those worked by moonlighting women averaged about 70 percent of those by men. About 30 percent of moonlighters worked from 8 to 14 hours a week on their secondary jobs. About 52 percent worked either 1 to 7 hours or 15 to 21 hours.

[1] Data on reasons for working at more than one job by race are tabulated for "black and other," in contrast to black only. The black and other group includes those who identified themselves in the enumeration process to be other than white. At the time of the 1970 Census of Population, 89 percent of the black and other population group were black.

Industries in which employees worked more than the average number of hours on secondary jobs, in May 1979, included construction, 16 hours, and manufacturing, 15 hours.

Moonlighters worked a weekly median of 40 hours on their primary jobs in May 1979, the same median as single jobholders, and for both white and black workers. Moonlighters who were self-employed in agriculture as a first job worked a median of 56 hours, the longest of any occupation, while unpaid family workers averaged 35 hours of work on their first jobs. ☐

FOOTNOTES

[1] This is an annual study based on data supplied by the May Current Population Survey.

[2] Also included as multiple jobholders are persons who had two jobs during the survey week because they were changing jobs. This group is very small—about one percent of all multiple jobholders in May 1979. Persons employed only in private households (such as housekeepers, launderers, gardeners, and babysitters) who worked for two or more employers during the survey week were not counted as multiple jobholders, because working for several employers is considered an inherent characteristic of this type of work. Also excluded were self-employed persons with additional farms or businesses and persons with secondary jobs as unpaid family workers.

[3] See Beverly L. Johnson, "Marital and family characteristics of workers, 1970–78," *Monthly Labor Review*, April 1979, pp. 49–52; and Janet L. Norwood and Elizabeth Waldman, "Women in the labor force: some new data series," U.S. Bureau of Labor Statistics, Report 575, October 1979.

[4] See Carol Leon and Robert W. Bednarzik, "A profile of women on part-time schedules," *Monthly Labor Review*, October 1978, pp. 3–12.

[5] The question asked is "What is the main reason that . . . worked at more than one job?" That question was also asked in May 1969, but only five reasons were tabulated at that time. Since May 1974, eight reasons have been tabulated, thus, the earlier data are not strictly comparable with the 1974–79 tables.

Percent working long hours shows first post-recession decline

GEORGE D. STAMAS

From 1978 to 1979, the incidence of long hours among full-time wage and salary workers dropped for the first time since the 1974–75 recession. The 18.8 million employees who put in workweeks of 41 hours or more in May 1979 were about 26 percent of all full-time wage and salary workers, down about 1 percentage point from 1978. Of those who worked long hours, about 43 percent received premium pay, the same proportion as in 1978 and well above the recessionary low of 1975. (See table 1.)

These data were gathered through a supplement to the Current Population Survey and relate to wage and salary workers with one job who worked 41 hours or more during the week ending May 12, 1979.[1] They do not include the 3.3 million multiple jobholders who worked more than 40 hours, even if they passed the 40-hour mark on their principal job. Nor do they include the 4 million self-employed who worked 41 hours or more.

Table 1. Full-time wage and salary workers who worked long weeks and those who received premium pay, May 1973–May 1979

[Numbers in thousands]

Year	All full-time workers	Worked 41 hours or more[1]		Received premium pay	
		Number	Percent of full-time workers	Number	Percent of those who worked 41 hours or more
1973	62,202	18,105	29.1	7,697	42.5
1974	63,714	17,564	27.6	7,302	41.6
1975	61,765	15,450	25.0	5,597	36.2
1976	64,546	16,679	25.8	6,621	39.7
1977	66,441	18,174	27.4	7,697	42.4
1978	69,428	18,977	27.3	8,136	42.9
1979	71,677	18,765	26.2	7,999	42.6

[1] Data are limited to wage and salary workers who worked at only one job.

The Fair Labor Standards Act, passed by Congress in 1938, mandated that premium pay of time and one-half the regular wage be paid to qualifying nonsupervisory workers for hours worked in excess of 40 per week. Over the years, the act has been amended and in 1979 its overtime provisions covered an estimated 53 million workers, 74 percent of all nonsupervisory workers, 59 percent of all civilian wage and salary workers.[2]

While the act sets the standard for most workers, premium pay for overtime begins before 40 hours for some workers. Public laws covering government contracts and Federal employment generally entitle workers to premium pay for hours worked in excess of 8 per day without regard to weekly hours. In addition, some collective bargaining agreements specify overtime after 35 hours a week or even less, after 8 or fewer hours a day or on some other basis.[3] Thus, the data on long hours presented here include some workers who are not on "overtime" despite exceeding 40 hours per week, while they exclude others who worked overtime, although their workweek was less than 40 hours.

Use of overtime

Even with the premiums for overtime specified in laws and union contracts, employers still use overtime hours to get out their product. Management uses overtime to cope with "disequilibrium phenomena," such as strikes, mechanical breakdowns, or bad weather. Also, because the cost per hour of hiring, training, and providing fringe benefits to addditional employees can exceed the cost per hour of premium pay, management sometimes orders overtime to meet increased demand, particularly of a temporary or short-term nature. Some

George D. Stamas is an economist in the Office of Current Employment Analysis, Bureau of Labor Statistics.

Table 2. Full-time wage and salary workers who worked long weeks and those who received premium pay by hours worked, May 1979

[Numbers in thousands]

Usual hours and premium pay	Hours worked: Worked 41 hours or more	Worked 41 to 48 hours	Worked 49 to 59 hours	Worked 60 hours or more

Received premium pay	7,999	4,748	2,357	894
Percent receiving premium pay	42.6	54.7	37.7	23.3
Usually worked 41 hours or more	12,895	4,630	4,859	3,404
Received premium pay	4,152	1,979	1,485	687
Percent receiving premium pay	32.2	42.7	30.6	20.2
Did not usually work 41 hours or more	5,871	4,055	1,390	424
Received premium pay	3,847	2,768	872	206
Percent receiving premium pay	65.5	68.3	62.7	48.6

NOTE: Because of rounding, sums of individual items may not equal totals.

economists think that rising fringe benefits have created a "fringe barrier" to new hirings by diminishing the relative cost of an overtime hour. They claim that the time-and-a-half premium is no longer a very strong deterrent to the use of overtime.[4]

However, a trend toward the increased use of overtime is not obvious in the general data presented here. During May 1973–79, from 25 to 29 percent of full-time wage and salary workers put in more than 40 hours a week, and at least 36 percent of those on long hours (and often about 42 percent) received premium pay. One in 10 full-time wage and salary workers put in more than 40 hours a week and received premium pay.

Of the 18.8 million workers on extended schedules during the May 1979 reference week, 12.9 million were reported as regularly working 41 hours or more. Only one-third received premium pay, compared with two-thirds of those who worked over 40 hours only occasionally. (See table 2.) Whether or not a person routinely worked long hours, the proportion earning premium pay for extra hours decreased as the number of hours worked increased.

More than three-fifths of the workers who routinely worked long hours put in more than 48 hours and about half spread the work over more than 5 days. In contrast, only three-tenths of those who seldom worked long hours worked more than 48 hours during the reference week.

Approximately 7.4 million workers in goods-producing industries and 11.4 million workers in service-producing industries put in weeks of 41 hours or more in May 1979, nearly the same as the preceding year. Although about the same proportion of workers were on long hours in goods production as in services (27.2 and 25.5 percent) workers in goods production were—as was the case in previous years—twice as likely to receive premium pay for long hours. (See table 3.) Within the service-producing sector, however, the proportion of workers who received premium pay for long hours ranged up to 50 percent or more in transportation and public utilities and Federal public administration. The latter group includes the postal service, in which 78 percent of the employees on long hours received premiums.

Agriculture is the anomaly among the goods-producing industries, with 53 percent of the workers putting in more than 40 hours but only 12 percent receiving a premium. Farmworkers are exempt from overtime provisions of the Fair Labor Standards Act.

Long hours in services down

The incidence of long hours in the goods-producing industries was about the same as in the previous year, but lower than in May 1977. However, it remained well above the recessionary low of 1975. The proportion of long hours used by employers in the service sector has fallen to a level as low as anytime in the 7-year period. This may be due partly to the gradual removal of the Fair Labor Standards Act's overtime exemptions for hotel, motel, and restaurant employees, which was completed in January 1979. This does not necessarily indicate weakness of the economy. On the contrary, employers—expecting strong demand for their goods or services—may have been more likely than in recent years to hire additional employees, rather than work those on board overtime.

State and local public administration bucked the trend of relatively little change in premium pay set by other industries. In State and local government, the proportion of workers on long hours receiving premium pay has shown a substantial increase during 1973–79. At the same time, the incidence of workers on long hours in State public administration has been decreasing.

Although white-collar and blue-collar employees are about equally apt to work long hours, the incidence of premium pay is much lower for white- than blue-collar workers. (See table 4.) Managers and administrators were among the most likely of all workers to put in long hours and the least likely to receive premium pay. Clerical workers were among the least likely to work long hours, but the proportion who received premium pay was comparable to that among blue-collar workers. Transport equipment operatives were about as likely as managers and administrators to work long hours and were the least probable of all blue-collar employees to receive premium pay. A higher proportion of other operatives received premium pay than any other occupation.

Table 4. Full-time wage and salary workers who worked 41 hours or more a week and those who received premium pay, by occupational group, May 1979

[Numbers in thousands]

Occupational group	May 1979		
	Number	Percent of full-time workers	Percent received premium pay
All occupations	18,765	26.2	42.6
White collar	9,691	26.2	23.8
Professional and technical workers	3,199	20.4	21.0
Managers and administrators	3,643	44.0	11.9

[1] Member of a labor union or of an employee association similar to a union or working at a job covered by a union or employee association contract.

[2] Percent not shown where base is less than 75,000.

The proportion of white-collar workers on long hours was lower in 1979 than in 1978, and had returned to a level as low as in any May in the preceding 6 years. Although the work schedules of blue-collar workers tend to be more cyclically sensitive (probably because the industries where they concentrate are particularly sensitive to business cycles) the number and percent of blue-collar workers on long weeks were about the same in May 1979 as 1 year earlier. About the same proportion of blue-collar workers received premium pay for long hours in 1979 as in 1973, while the proportion of white-collar workers had risen slightly.

The proportion of service workers on long hours dropped over the 1973–79 period, while the proportion receiving premium pay, though off from the May 1978 level, rose considerably over the May 1973 rate, from 25.7 to 36.8 percent.

Negotiations by unions

Workers covered by union contracts make up three-tenths of the full-time wage and salary workers.[5] In some cases, unions have negotiated shorter standard hours and higher overtime premiums than provided by law, as well as the right to a fair share of overtime and the right of individual workers to refuse overtime. Table

Table 6. Full-time wage and salary workers who worked long weeks and those who received premium pay, by selected characteristics, May 1979

[Numbers in thousands]

Characteristic	Worked 41 hours or more		Received premium pay	
	Number	Percent of full-time workers	Number	Percent of those who worked 41 hours or more
Men	14,778	32.7	6,191	41.9
Age: 16 to 19 years	420	24.5	244	58.1
20 to 24 years	1,994	31.6	1,127	56.5
25 to 54 years	10,666	34.4	4,254	39.9
55 years and over	1,696	27.6	565	33.3
Race: White	13,761	34.2	5,642	41.0
Black and other	1,017	20.7	549	54.0

Other	3,276	16.2	1,453	44.4

[1] Data include workers who either are members of a labor union or of an employee association similar to a union, or whose job is covered by a union or employee association contract.

NOTE: Because of rounding, sums of individual items may not equal totals.

5 shows that the proportion of union workers on long hours was only two-thirds that for nonunion workers, while the proportion that received premium pay for long hours was twice as large. This relation pervades the major occupational and industrial groups, though the relative differences between the union and nonunion rates vary.

The frequency of long hours among women is only half of that among men. (See table 6.) For those women who did work long hours, their workweeks were short relative to those of men; 58 percent of the men worked more than 48 hours compared to 39 percent of the women. A larger proportion of men than women regularly work long hours, as well. Women, however, were slightly more likely to receive premium pay than men. Married men worked long hours more frequently than men who were never married but with little difference from widowed, separated, or divorced men. Among women, long hours varied less with marital status.

Black workers were much less likely than white workers to put in long workweeks. Among the full-time wage and salary workers, 28 percent of whites and 16 percent of blacks worked long hours in May 1979.[6] However, 53 percent of the black workers earned premium pay for their long hours, compared to 42 percent of the white workers. Disproportionately small numbers of blacks work in professional, technical, or management occupations, where long hours are more common and premium pay less so. The differences in the incidence of premium pay between black and white workers was greater among men than women.

Individuals 25 to 54 years old had the highest incidence of long hours. However, the likelihood of receiving premium pay declines in successively older age categories, dropping from 58 percent for teenagers to 34 percent for persons 55 years and over. A factor in this is that many older workers have taken supervisory positions where premium pay provisions do not apply. Even when the worker may have the choice of accepting premium pay, the combination of higher income and progressive income tax schedules may make older workers more likely to take compensatory time off for long hours rather than premium pay. ☐

FOOTNOTES

[1] The Current Population Survey is a survey of households, numbering 56,000 in May 1979, which is conducted for the Bureau of Labor Statistics by the Bureau of the Census. A worker reported as receiving premium pay is one who answered "yes" to the question: Did . . . get a higher rate of pay, like time and a half or double time, for hours . . . worked over 40? Data on premium pay are not available for the 3.3 million wage and salary workers who held two or more jobs totaling 41 hours or more. For information on these workers, see Edward S. Sekscenski, "Women's share of moonlighting nearly doubles during 1969–79," *Monthly Labor Review*, this issue.

Although the data presented here provide considerable information on the number and characteristics of workers on extended schedules and on their receipt of premium pay, they cannot measure with precision the number of overtime hours. For data from employer payroll records on overtime hours paid production workers in manufacturing, see *Employment and Earnings* (Bureau of Labor Statistics) monthly, table C-2.

MacDonald, "The Fringe Barrier Hypothesis and Overtime Behavior," *Industrial and Labor Relations Review*, July 1966, pp. 562-569, and, most recently, Arthur R. Schwartz, *The Effects of Benefits and Overtime Costs on the Short Run Cyclical Demand for Labor in the Automobile Industry in Michigan*, Ph.D. dissertation, the University of Michigan-Wayne State University, Ann Arbor, Michigan, January 1979.

[5] In this report, a union worker is defined as a member of a labor union or employee association similar to a union or a worker whose job is covered by a union or employee association contract.

[6] "Black workers" refers to all workers who are not white. According to the 1970 Census of Population, black people make up about 89 percent of the "black and other" population.

Research Summaries

Tracking individual earnings mobility with the Current Population Survey

FRANCIS W. HORVATH

The earnings of individual workers, matched in two consecutive May Current Population Surveys, increased more over the year ended in May 1978 than did earnings averages for all wage and salary workers. While median hourly earnings rose 7.0 percent between May 1977 and May 1978, the corresponding median level of change across matched individuals was 9.1 percent. However, this and other findings in this report must be interpreted with caution due to several complications inherent in the formation of the sample and other restrictions outlined below.

The data in this report are based on unweighted sample counts from a match of the Current Population Surveys (CPS) of May 1977 and May 1978. The CPS is a monthly cross-sectional sample which provides the basic national data on employment and unemployment. In May of each year, supplemental data have been collected on usual weekly earnings, usual hours worked per week, as well as actual hourly earnings for those employed during the sample period.[1]

While the CPS earnings data refer to only one period covering the given reference week, it is possible to create a year-to-year longitudinal subsample by virtue of the survey design. To minimize the reporting burden on the respondents in the survey, as well as to improve the reliability of estimates of change, households are rotated in and out of the sample in a predetermined pattern. Specifically, after a household address enters the sample in a given month, it remains in the sample during the next 3 months, is dropped for 8 months, and then returned for a final 4 months. This rotation system, known as a "4-8-4", provides for maximum overlaps of 75 percent in the month-to-month estimates, and 50 percent in the year-to-year sample[2] That is, the questions asked in May of one year will be asked (potentially) a second time of one-half the households in the sample the following May.

Using those households common to both May surveys, it is possible to obtain a subsample of persons containing information on all the questions asked in each survey. Thus, it becomes possible to track the flows of individual persons from one labor force and earnings status to another by comparing answers from the two surveys.

Sample selectivity. The gap between the potential of the theoretical match and that actually achieved is very wide, however. Several biases are known to exist in the matched data which should temper any conclusions based on this source of data. Most significantly, it should be noted that the possibility of a year-to-year longitudinal match is a byproduct of the sample design. The CPS is a survey of households—persons living in those households are not the basic units of the sample design. Thus, if a person were to move out of a surveyed household before the end of the sample period, and a new occupant were to move in, the new resident would be in the survey in all the subsequent survey months. The one who leaves is not followed and, thus, is "lost" to the sample. When the household address is "matched" with its previous information, its occupants will differ and, therefore, cannot be used in the longitudinal sample.

In the light of these considerations, the matched sample is not a random sample of the population, and cannot be used appropriately by any statistical procedure (such as ordinary least squares) which treats it as such.[3] Every characteristic known to be positively associated with mobility will be disproportionately "lost" in the matched sample. This includes characteristics such as age, race, and sex.[4] The matched sampling process retains more of those persons who are older, white, and more likely to be women. This is shown in table 1, which displays the sample representation of the match used in this report by several demographic characteristics.

The most striking feature shown by the data in table 1 is the systematic loss of young persons by the matching process. About 50 percent of the young persons 16–

Francis W. Horvath is an economist in the Office of Current Employment Analysis, Bureau of Labor Statistics. Daniel Glazer of the same office created the matched file discussed in this study.

24 years of age in May 1977 are not matched in the next year. In addition, there appears to be a slightly greater loss of blacks and others than whites, and a slightly higher retention of women than men in the matched sample.

In addition to the loss of movers, the matched sample is incomplete for other reasons. Information is missing for persons who died and there is no way of separating them from those who moved. Response and coding errors may also present a problem. If the respondent changes some answers on which the match is keyed (such as race or age), he or she may not be treated as a match. Any incorrectly recorded or coded information in either year can cause identical persons to be rejected by the matching procedure.

Another problem with the sample is that the data are not inflated to population estimates using the weights assigned to persons in the CPS. In any month, the weights used to inflate the raw sample counts are based on the answers received in that particular sample month. This implies that the two separate weights for 1977 and 1978 need not necessarily be equal. While some average of the two weights could be defined, this procedure would not have a reliable statistical foundation.

Wage change selectivity. Another layer of selectivity is imposed on wage change comparisons by the restriction that persons remain in the employed labor force for both periods. Questions on usual weekly earnings and actual hourly earnings are asked only of those persons who were employed in the reference week, excluding the self-employed and unpaid family workers. Obviously, to compute any measure of change in average hourly earnings or usual weekly earnings, it is necessary to have observations for both years. Because the wage change sample is limited to employed persons who responded to the questions in both years with dollar amounts, it is even less representative of the population. At this level, groups with high probabilities of leaving employment are lost, as well as those who are unable or choose not to answer the earnings questions in both reference periods. For example, 59 percent of 2,824 black and other men were matched in 1978, but only 19 percent were employed in both years and provided sufficient information to compute a change in average hourly earnings.

Table 1. Sample representation by selected demographic characteristics

Characteristic	Total	In match	Not in match[1]	Match as a percent of total potential match
Total	55,062	36,811	18,251	66.8
MEN				
16 to 24 years	5,966	2,886	3,080	48.4
25 to 64 years	16,491	11,590	4,901	69.7
65 years and over	3,266	2,500	766	76.5
WOMEN				
16 to 24 years	6,488	3,085	3,403	47.5
25 to 64 years	18,281	13,243	5,038	72.4
65 years and over	4,570	3,507	1,063	76.7
White men	22,889	15,302	7,587	66.8
White women	25,776	17,554	8,222	68.1
Black and other men	2,824	1,674	1,150	59.3
Black and other women	3,523	2,241	1,282	63.2

[1] These persons were in rotation groups 1–4 in May 1977, and therefore, in the potential match, but were not surveyed again in May 1978.

Despite these caveats, the underlying earnings mobility data are interesting in their own right. This data base contains more observations than most special-purpose longitudinal surveys and, thus, permits a range of dynamic analysis.

Annual flows. Table 2 shows the employment status and hourly earnings level for those reporting hourly pay in May 1977 and May 1978. In addition to those in the earnings match, the table includes the complete distribution for all persons in rotation groups 1–4 in May 1977 and those in rotation groups 5–8 in May 1978. With the level of detail shown here, it is possible to trace the changes in actual hourly earnings and labor force categories within fairly small wage brackets over the course of the 2-year period.

For example, reading across the row marked "$2.30," which was the minimum wage in the first year, 505 matched persons were employed and paid by the hour again in May 1978; 107 worked at the new minimum wage of $2.65; 32 of the 505 became the unemployed in the second year and 101 dropped out of the labor force. Three hundred and forty of those employed at the minimum wage in May 1977 could not be followed in May 1978.

Examination of the "unemployed" and "not in the labor force" categories crossed by previous year's earnings yields some interesting findings. Persons leaving employment and becoming unemployed tend to have higher wages than those employed persons who leave the labor force. Similarly, persons entering employment who were unemployed in the first year seem to have higher 1978 earnings levels than those who enter employment from outside the labor force. It seems that low-wage workers are more likely to move into and out of the labor force than higher wage persons, who typically are looking for work if not employed.

Several comments can be made about those not responding to the earnings questions in both years. If nonresponse is concentrated in particular demographic or earnings groups, it could complicate wage change comparisons. For example, 17 percent of black and other men who respond to the actual hourly earnings questions in the first year and should respond in the

[1] Includes those paid by the hour but not reporting a dollar amount.

[2] Includes all those not paid by the hour, those not answering, and those not asked the question.

[3] There were 18,251 persons in rotation groups 1-4 in May 1977 who were not matched with May 1978 information.

[4] There were 16,631 persons in rotation groups 5-8 in May 1978 who could not be matched with May 1977 information.

second did not, compared with only 12 percent of the white men in similar circumstances. Nonresponse in the second year tends to rise slightly at higher 1977 earnings levels.

Earnings mobility. The most striking feature of the earnings change data is that, for those matched, the percentage change in each measure of earnings is large. The median percentage increase in earnings per hour for individuals paid by the hour was 9.6 percent, usual weekly earnings were up by 9.1 percent, and average hourly earnings rose by 9.4 percent. By comparison, from May 1977 to May 1978, median hourly earnings for all wage and salary workers increased 7 percent.

The differences in the results between the matched sample and the two individual May surveys may be related to work experience. If labor force experience does indeed produce higher earnings levels, those workers common to both periods are most likely to have increased their level of experience by 1 year.[5] This is not true of the two separate earnings distributions. These figures are based not only on those employed in both periods, but also on the relationships between levels of wages and flows of persons entering and leaving employment. The differences between the aggregates and the individual change measures might be more pronounced the greater the volume of employment turnover in the group.

Table 3 describes the percent change in actual hourly earnings, average hourly earnings, and usual weekly earnnings by selected demographic characteristics. In addition, the table lists the 1978 status of all persons employed during May 1977, so that the various layers of selectivity may be seen in perspective.

The percentage change in earnings for all three measures tends to be highest for those groups with the greatest flows out of employment. For example, while young women age 16-24 employed and paid by the hour in both periods increased their actual hourly earnings by 14.7 percent, the percentage of young women employed in both periods was among the smallest, 78.6 percent. Among employed white men, 92.9 percent were employed the following May, and those answering actual earnings questions in both surveys showed an increase of 9.2 percent. For white women, only 84.8 percent were employed again the following May, but those answering both actual hourly earnings questions had a slightly higher increase, 10.1 percent.

It should be noted that the groups with the highest percentage changes in the earnings measures typically begin from a low base. For example, persons earning the minimum wage in both May 1977 and May 1978 moved from $2.30 an hour to $2.65. This small absolute increase of 35 cents becomes a large relative increase of 15.2 percent when related to the $2.30 base.

Average hourly earnings (usual weekly earnings divided by usual hours worked) rose at about the same rate as actual hourly earnings. Again, prime working-age men showed the smallest increases, and those groups not strongly attached to the labor force showed the largest changes. The representation of the sample runs at about one-third of those surveyed in May of

Table 3. Tracking individuals employed in May 1977 and May 1978

Characteristic	Total	Men					Women				
		White	Black and other	Age 16–24	Age 25–64	Age 65 and over	White	Black and other	Age 16–24	Age 25–64	Age 65 and over
Employed in May 1977	31,962	17,026	1,726	3,771	14,771	684	11,654	1,556	3,255	9,594	361

Percent change in usual weekly earnings[1]	9.1	8.5	8.5	18.0	7.8	3.6	10.2	8.9	16.7	9.2	2.4

[1] Data are median percent changes based on individuals in the respective percent change universe.

1977 for most groups, although somewhat lower for very young and older workers.

Usual weekly earnings followed the same general pattern as actual and average hourly earnings. Percent changes were highest for young men and women, both groups which are likely to get "lost" in the matching process. Usual weekly earnings were higher for white women than white men, which may reflect, in part, a greater increase in hours worked for women. Sample followup was slightly more than one-third of those employed in May 1977 for most groups. ☐

FOOTNOTES

[1] See *Weekly and hourly earnings data from the Current Population Survey*, Special Labor Force Report 195 (Bureau of Labor Statistics, 1977), for a more complete discussion of this source of data. May 1978 was the last year in which these items were collected for the full sample. Beginning in October 1978, earnings questions were asked of persons in the two outgoing rotation groups each month and will be published quarterly. These new data will not be strictly comparable to previous earnings information.

[2] See *The Current Population Survey, Design and Methodology*, Technical Paper No. 40 (Bureau of the Census, 1978), for a complete description of the survey design.

[3] See G. S. Maddala, "Self Selectivity Problems in Econometric Models," in P. Krishniah, ed., *Applications of Statistics* (Amsterdam, North Holland Publishing Co., 1977).

[4] The percentage of persons who change their household each year in the United States has been relatively constant at about 20 percent since the question of previous residence was first asked. However, mobility varies sharply by several demographic characteristics most notably by age as shown below in the most recent 1-year mobility figures from the March 1976 Current Population Survey:

	Percent changed households in year ended March 1976
Total	17.1
Age groups:	
15–19	16.1
20–24	38.0
25–29	32.6
30–34	20.3
35–44	13.4
45–54	8.4
55–64	7.0
65 and over	5.6
Black	18.0
White	17.0
Men	17.5
Women	16.8

[5] There are only two discrete observation points and the amount of work experience between these two points cannot be determined.

The extent of alcoholism among Air Force employees

T. ROGER MANLEY, CHARLES W. MCNICHOLS,
AND MICHAEL J. STAHL

An extensive survey of Air Force civilian employees reveals that almost 7 percent are problem drinkers.[1] But a conservative classification scheme as well as voluntary participation in the 1978 survey, the first of its type among Federal employees, suggests that the number of problem drinkers may be substantially understated.

We administered questionaires to 13,146 U.S. Air Force civilian employees during October-November 1978, of which 9,939 responded. The results showed that 6.9 percent of these respondents experienced some

McNichols is an associate professor of management at the Air Force Institute of Technology, Wright-Patterson Air Force Base, Ohio. Michael J. Stahl is an associate professor of management at Clemson University, Clemson, South Carolina.

impairment of their job performance because of drinking. The overall toll on productivity due to missed days, working at lower levels of efficiency, and irregular hours was computed to be .359 day per person during 1978.

The results

Table 1 presents a summary of responses to survey items used to establish physical dependence on alcohol. To ensure that respondents understood the wording of the symptom describing tremors ("shakes"), two differently worded items were used. A positive response to either or both was counted as one symptom of physical dependence. According to our criteria, 1.1 percent of the respondents were physically dependent upon alcohol.

The 13 serious consequences related to drinking, as shown in table 2, cover an individual's worklife, physical health, and social/family life. They suggest that family life might be the part of the individual's life which is most severely or frequently affected, or both.

In computing lost working time associated with alcohol consumption, one quarter of a day lost was counted for each reported instance of working at a lower level of performance, being "high" at work, or arriving late or leaving early. It is of interest to note that 11 percent of the employees worked at a lower level of performance because of drinking; 5.5 percent missed at least 1 entire day; 5 percent arrived late or left early; and 6 percent were "high" at work on at least one occasion. We conservatively estimated that an average of .359 days per employee was lost last year because of drinking. (See table 3.)

Our figures show that 20 percent of the respondents abstained from using alcohol during the preceding year, 52 percent consumed up to 1 ounce of ethanol (pure alcohol) per day, 8 percent consumed between 1 and 2 ounces per day, 6 percent consumed between 2 and 5 ounces per day, and 1 percent reported consuming over 5 ounces of pure alcohol per day.[2]

Psychological dependence

In addition to symptoms of physical dependence, the survey contained six questions which were found to provide an effective overall measure of psychological dependence.

Table 1. Workers reporting symptoms of alcohol dependence during year

[In percent]

Symptom	Never	Has happened, but not in past year	1-11 days per year	One or more days per month
Tremors ("shakes")	92.1	4.0	2.7	1.2
Tremors (morning shakes)	91.5	3.8	3.6	1.1
Morning drinking	93.2	3.2	2.3	1.3
Memory loss (blackouts)	86.5	7.9	4.5	1.1
Loss of control	91.3	4.0	4.5	1.1

NOTE: Item wording for all symptoms was specified as being related to drinking.

Table 2. Workers reporting alcohol-related consequences during year

[In percent]

Consequence[1]	Never	Happened, but not in past year	Happened once or more in past year
Received disciplinary action	98.4	0.8	0.8
Received lower performance rating	98.2	0.8	1.0
Illness kept me from work for a week or more	97.4	1.3	1.3
Hospitalized for 2 or more days	97.9	1.7	0.4
Visited a physician two or more times	97.7	1.9	0.4
Had an accident causing self-injury	97.4	1.8	0.8
Had an accident causing injury/property damage	97.1	2.2	0.7
Spouse left because of drinking	98.5	0.7	0.8
Spouse threatened to leave but did not	87.4	7.8	4.8
Arrested for drunken driving	94.4	4.4	1.1
Arrested for non-driving offense	93.0	5.6	1.4
Spent time in jail	95.8	3.4	0.8
Got into fight(s)	93.9	4.1	2.0

[1] All incidents were specified as caused by or related to alcohol consumption and occurring during the past year.

By using factor analysis, we determined that the six questions measured a single underlying phenomenon (accounting for 62 percent of the variance in the responses) and could be summed with unit weights to provide a single overall measure of psychological dependence. Scores ranged from the lowest possible, 6, to the highest possible, 30. The mean score for all respondents was 8.33, with a standard deviation of 3.32. The mean score for respondents classified as physically dependent was 14.38, and 12.05 for those classified as adversely affected.

We conducted a number of tests to compare the psychological dependence scores of respondents according to various parameters. We found that respondents who scored high on psychological dependence were more likely to report more symptoms of physical dependence than other employees; more adversive effects related to drinking; higher scores on an intoxication index; more days lost from work because of drinking; and, higher consumption of alcohol. These and other findings suggest that psychological dependence, as measured by the six survey items, can be an effective discriminator for alcohol-related problems.

Work and alcohol-related problems

Although some notice has been taken of alcohol problems vis-a-vis job satisfaction and work involvement or leisure activities, the literature remains somewhat sparse and inconclusive. However, the little that can be found suggests that individuals with drinking problems tend to be somewhat compulsive about their work and uncomfortable with leisure time.[3]

Nevertheless, our study of alcohol-related variables and variables dealing with work suggests that individuals with drinking problems may not be so compulsive about their work, nor do they enjoy it.

Executive stress as a cause of alcoholism and various other stress-related diseases have recently received a good bit of attention in the press.[4] Examination of stress scores (the sum of responses to a six-item measure of overall stress) and alcohol-related variables, such as adverse consequences, suggests individuals with low and high stress scores are more apt to report having experienced adverse consequences than are respondents who report some moderate level of stress. Interestingly, these data seem to support theory in preventive medicine as well as the observations of stress management specialists.[5]

Alcoholism and alcohol-related problems were elevated to a status requiring official notice and concern by Federal agencies with the passage of the Comprehensive Alcohol Abuse and Alcoholism Prevention, Treatment, and Rehabilitation Act of 1970. This law directed that the Civil Service Commission and the Secretary of Health, Education, and Welfare make certain that all Federal agencies and departments develop and maintain appropriate prevention, treatment, and rehabilitation programs and services for Federal employees. Similar legislation has been passed by a number of State legislatures.

As highlighted by a 1977 GAO report[6] and later by the HEW Secretary, alcoholism and problems associated with alcohol deserve national concern.[7] Although some dimensions of the problem have been estimated and can be found in sources such as the HEW report to the Congress, until now virtually no scientifically designed epidemiological research has been conducted among public sector employees. Some indication of the belatedness of public sector employer interest in this area can be gained by noting that of the 2,400 U.S. employers with occupational alcoholism programs in 1977, only 400 were in the public sector, and most of these were of relatively recent vintage.

Sample randomly selected

Our survey sample was randomly selected and stratified by grade. Questionnaires were administered in two ways: respondents were requested to report to a central location to fill out the survey instrument, or they were mailed a questionnaire at their work locations. Completion of the questionnaire was voluntary and all respondents were guaranteed anonymity. Instructions accompanying the survey emphasized that the researchers from the Air Force Institute of Technology would be the only individuals who would have access to decoded answer sheets.

Table 3. Workers reporting lost working time due to drinking

[In percent]

Item	Any occurrence	Occurrences resulting in 3 lost days or more	Estimated days lost per person[1]
Missed an entire workday	5.5	1.9	.161 days
Worked at lower level of performance than normal[2]	11.4	5.1	.118
Arrived late or left early	5.0	2.2	.047
Was "high" at work	6.0	1.9	.066
Days lost	–	4.3	.359

[1] One occurrence counted as the loss of 25 percent of a workday.

[2] Counted only to the extent that days "high on duty" exceeds days of "lower performance than normal" for that person (to avoid possible double counting).

Of the 9,939 Air Force employees responding, 3,098 did so by mail and 6,841 in groups. The response rates were: overall, 75.6 percent; group-administered, 78.4 percent; and mail-administered, 70.2 percent. We do not know what proportion of nonrespondents to mail-administered surveys actually received questionnaires. Of the 21.6 percent nonrespondents to group administration, 1.7 percent refused to participate. The remaining 19.9 percent were notified, but did not show up at the scheduled time.

We emphasize the 24.4-percent nonresponse rate because we consider it critical. As suggested by other researchers, we recognize that a disproportionate number of individuals with drinking problems were probably among the 3,207 nonrespondents. As a result, we consider the data to represent a "lower-bound" or overly optimistic assessment of the extent to which alcoholism and alcohol-related problems exist among Air Force employees.[8]

The typical respondent was a 43-year-old white male who was married, had two dependents, was a high school graduate, and whose supervisor was also a civilian. Thirty-six percent of the respondents were women (average age 35 years) and 25 percent, minority group members. The distribution of respondents according to standard organizational and personal variables closely matched those of the overall Air Force civilian work force. Overseas employees, because of ground rules established to protect respondent anonymity, were underrepresented.

The questionnaire

In constructing the questionnaire,[9] we attempt to focus on two aspects of alcohol-related problems: addiction/physical dependence upon alcohol and serious consequences associated with the consumption of it. Respondents who placed themselves in the first (and more serious) category we call *alcohol dependent.* Respondents who report having experienced one or more serious consequences we call *adversely affected.* More formal definitions are:

> *Alcohol dependent:* An individual who exhibits observable, chronic behavioral problems which imply physical dependence on alcohol or physical impairment akin to dependence.
>
> *Adversely affected:* An individual who experiences one or

more serious consequences, whose average daily intake of alcohol is at a "high risk" level (that is, a volume at which damage to the liver can be presumed to occur), or who loses 3 or more work days because of drinking.

In performing the calculus to identify respondents to be placed in each category, we relied on self-reports of having experienced two or more of four physical dependence symptoms *at least once a month* over the past 12 months to establish alcohol dependence. A respondent who was adversely affected experienced one of 13 serious consequences at least *once during the past year;* consumed 5 or more ounces of pure alcohol daily; or missed at least three working days.

Survey items measuring alcohol consumption included consideration of the type of beverages consumed during the past 30 days, the frequency of drinking during the past 30 days and the past year, and the volume of alcohol consumed during the past 30 days and the past year. Items measuring productivity loss (days lost from work) included consideration of time lost because an individual was sick, "high" on the job, hung over, absent, or arrived late or left work early.

Also included in the 109-item questionnaire were measures of psychological dependence, stress/tension, work involvement, and job satisfaction. In addition, we included standard demographic variables which had been identified as meaningful in other alcoholism studies.

We believe that our data mark the first time that a large-scale research effort has been conducted on the subject of alcoholism and alcohol-related problems among Federal employees.

The often used approximation of 6 percent of the Federal employee work force having drinking problems is clearly ultra-conservative. Although we made use of self-reports (which notoriously understate quantity and symptomatic reports) and a version of the very conservative Rand classification scheme, almost 7 percent of the population was still identified as having significant drinking problems. The data also clearly show that misuse of alcohol costs the employer in terms of absenteeism, lowered efficiency, employee sick time, and on-the-job accidents which cause injuries and damage property. Alcohol costs the individual in terms of illness, impaired functioning, decreased personal control, and strained interpersonal relations. The fact that marriages and families suffer is also clearly indicated by the data. Correlated with problem drinking are decreased job satisfaction and work involvement, and increased stress and psychological dependence.

In many respects, employee alcoholism and alcohol-related problems have been like the weather: "Everyone talks about it but. . ." A law dealing with alcoholism among Federal employees has been in effect for almost a decade, and recent research suggests that alcoholism among women and teenagers is gaining in intensity; yet little organizational energy and resources are devoted to efforts to solve the problem, which costs so dearly in human suffering and lost productivity.

While there can be no doubt that the medical model of alcoholism as a disease holds for the alcoholic who is physically dependent on alcohol, it is also true that for many, alcoholism results from a progressive sequence of events (often easily observable by members of the family, friends, supervisors, and by the potential alcoholics themselves). Identification and treatment programs, if they are programs in more than name, can identify individuals with problems and offer treatment to potential alcoholics on a voluntary basis. For relatively modest investments in occupational alcoholism programs, organizations can realize significant returns on previous investments in their human resources. These returns equate to higher productivity, a heightened quality of life, and responsible organizational citizenship. □

FOOTNOTES

[1] The research described in this report was initiated at the request of the U.S. Air Force Director of Civilian Personnel who, in attempting to comply with the Comprehensive Alcohol Abuse and Alcoholism Act of 1970, determined that a scientifically designed research effort was needed to estimate the prevalence of alcohol-related problems and the consequences of those problems among USAF civilian employees.

[2] Note that 5 ounces of alcohol would be the equivalent of 12.5 one-ounce shots of 80 proof whiskey or 8.3 twelve-ounce cans of 5 percent beer.

Foreign Labor Developments

U.S. rejoins ILO: the agenda for 1980's stresses human rights

TADD LINSENMAYER

The 66th session of the International Labor Conference will convene in Geneva, Switzerland early next month. An official tripartite U.S. delegation will participate in this annual International Labor Organization gathering for the first time since 1977,[1] when the United States withdrew from that organization. The conference will take up a number of crucial labor issues involving working conditions and human rights, issues that are likely to represent a major part of the work of the ILO during the 1980's.

U.S. withdrawal

The historical relationship of the United States with the ILO has been marked by periods of warm support followed by disillusionment.

Although Samuel Gompers chaired the committee that drafted the original ILO charter in 1919 (as part of the Treaty of Versailles), the United States did not join the organization until 1934. During World War II, when the League of Nations withered, the United States strongly supported the ILO's continued existence and hosted the historic 1944 conference that adopted the Declaration of Philadelphia, setting forth the organization's principles and purposes.

The 1970's, however, saw U.S. support for the ILO decay and eventually break over a number of serious issues.

Beginning in 1970, the U.S. Congress voted to withhold its contribution to the ILO budget (25 percent of the total), citing its concern with growing Soviet influence and the nonobservance of fundamental ILO principles and procedures. U.S. funds were restored in 1973, but the resumption of U.S. support was followed shortly by even sharper U.S. complaints about misdirected ILO activities.

In 1975, following a decision by the ILO conference to grant observer status to the Palestine Liberation Organization, Secretary of State Henry Kissinger formally notified the ILO's Director General that the United States would withdraw from the organization in 1977 unless progress was made on the following four issues of major U.S. concern:

1. *Erosion of tripartism.* U.S. concern was triggered by efforts of some ILO members to impose restrictions on the independence of worker and employer delegates to ILO meetings.

2. *Selective concern for human rights.* Although ILO machinery for investigating violations of ILO human rights standards worked well in most cases, one group of countries—principally the Communist states of Eastern Europe—successfully used political influence to gain relative immunity from the application of that machinery.

3. *Violation of due process.* The ILO's human rights machinery protects the rights of accused governments by requiring an objective investigation of the facts. But in some cases, this due process right was ignored by conference participants who adopted politically inspired condemnatory resolutions.

4. *Politicization of ILO meetings.* In far too many cases, delegates to ILO meetings introduced political issues which were totally extraneous to the work of the ILO and which detracted from the organization's legitimate responsibilities.

Because the ILO failed, in the U.S. view, to make satisfactory progress on these issues in the intervening 2 years, President Carter ordered U.S. withdrawal from the ILO in November 1977.

Recent progress

Following U.S. withdrawal, a majority of ILO delegates—governments, workers, and employers—successfully joined together to promote a number of important reforms. The 1979 conference, for example, adopted a new procedure permitting voting by secret ballot to protect the independence of worker and employer delegates.[2] In November 1978, the ILO Governing Body censured Czechoslovakia for violating ILO standards concerning discrimination in employment. More recently, the Governing Body has initiated investigations into alleged violations of trade union rights in the Soviet Union and Poland.

The principle of due process was strengthened by the decision of the 1978 Conference to reject a proposal to extend the life of a 1974 resolution criticizing Israel without benefit of any investigation. A special working party of the ILO is currently giving serious consideration to a new procedure to screen out future resolu-

---

Tadd Linsenmayer is Assistant Director, Office of International Organizations and Technical Assistance, Bureau of International Labor Affairs, U.S. Department of Labor.

tions violating due process principles. Finally, the level of debate in ILO meetings on extraneous political issues has significantly diminished.

A special U.S. Cabinet-level committee on the ILO—chaired by Secretary of Labor Ray Marshall and including Secretary of State Cyrus Vance, the Secretary of Commerce (Juanita Kreps, Philip Klutznick), National Security Adviser Zbigniew Brzezinski, the AFL-CIO President (George Meany, Lane Kirkland), and Dr. David Grove, President of the U.S. Council of the International Chamber of Commerce—carefully examined these and other developments during the summer of 1979. The committee concluded that although not all of the issues of concern to the United States had been fully resolved, the ILO had made significant progress. Moreover, the committee agreed that continued progress in reaching the fundamental goals of the ILO was now more likely if the United States resumed active membership.

As a result of this review, the committee unanimously recommended to the President that the United States rejoin the ILO. Acting on this recommendation, President Carter announced the U.S. return, effective February 18, 1980.

1980 conference issues

The significance of the U.S. return can be measured by, among other things, its potential contribution to ILO technical programs, starting with an active U.S. presence during the June 1980 conference. That conference will consider the issues that will underlie the major ILO programs during the 1980's.

The conference has four major technical issues on its agenda: older workers; equal opportunities and equal treatment for men and women workers; safety and health in the working environment; and promotion of collective bargaining.

Significantly, all four issues involve aspects of human rights. For older workers and women, job discrimination continues to represent a serious concern. Some observers also feel that certain early ILO conventions, designed initially to protect women workers, resulted instead in promoting a system of discriminatory labor standards, which actually limited the employment opportunities of women workers.

The question of occupational safety and health also involves serious moral and human rights aspects. The ILO constitution and other international accords recognize that workers must be protected on the job as a matter of right, not privilege. Moreover, an increasing number of governments and worker organizations are expressing concern that countries which refuse to adequately protect workers' health may be reaping—at workers' expense—an unwarranted competitive advantage over countries which provide adequate worker protection.

Collective bargaining remains an important and recognized human right, one which is all too frequently compromised in the name of economic development.

Other important issues will also be considered by the 1980 conference. The committee which supervises the application of ratified ILO labor standards, for example, will consider whether to modify or, as some governments have proposed, eliminate entirely the so-called "special list" and "special paragraphs." These devices allow the conference to highlight flagrant violations of workers' human rights. The majority of delegates will likely favor retention of these important tools.

A committee on structure will consider proposals to modify the organization of the ILO, including the size and composition of the Governing Body. Another committee will examine any resolutions submitted by conference delegates.

The results of this conference will provide important indications of the ability of the ILO to tackle those serious technical issues for which it has a unique competence. A successful conference could well mark the start, after the troubled 1970's, of a new decade of achievement for the ILO. ☐

—— *FOOTNOTES* ——

[1] Delegations to ILO conferences include independent representation from governments, as well as worker and employer organizations.

Major Agreements Expiring Next Month

This list of collective bargaining agreements expiring in June is based on contracts on file in the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more.

Employer and location	Industry	Union[1]	Number of workers
Acme Markets, Inc. (Pennsylvania)	Retail trade	Food and Commercial Workers	1,900
Allis-Chalmers Corp. (Pennsylvania)	Machinery	Machinists	1,100
Aluminum Co. of America (Interstate)	Primary metals	Auto Workers (Ind.)	1,300
Associated Building Contractors of Northern Ohio, Inc. (Ohio)	Construction	Carpenters	1,500
Associated General Contractors of America, Inc.	Construction	Carpenters	1,500
Alaska Chapter, 2 agreements	Construction	Carpenters and Teamsters (Ind.)	1,800
California Chapter	Construction	Operating Engineers	14,000
California Chapter	Construction	Plumbers	25,000
California-Northern Chapters, 4 agreements	Construction	Carpenters; Laborers; Plasterers and Cement Masons; and Teamsters (Ind.)	44,000
San Diego Chapter, 2 agreements (California)	Construction	Building and Construction Trades Council	7,400

Developments in Industrial Relations

Administration announces new anti-inflation plan

President Carter on March 14 announced a new anti-inflation program that he said would restore "discipline" to both Government and American consumers without imposing mandatory wage and price controls. He accepted the Pay Advisory Committee's recommendation that annual pay increases fall within a 7.5- to 9.5-percent range. (See *Monthly Labor Review,* March 1980, pp. 55–56.) The President also indicated that he will ask the Congress to increase the staff of the Council on Wage and Price Stability to permit closer monitoring of wage increases and to require smaller firms with annual sales of $100 million or more to report quarterly price actions to the council. (Presently, only firms with annual sales of $250 million or more are required to report.)

The new plan stressed budgetary restraints, calling for spending cuts of $18 billion during fiscal 1981 (which begins October 1, 1980) as well as cuts in the current fiscal year. The reduction will be achieved by deferring, reducing, or canceling most of the new or expanded programs included in the budget for fiscal 1981, submitted to the Congress on January 28; cutting expenditures for personnel operations and maintenance in Government; and reducing Federal civilian jobs by more than 20,000 by October 1980.

Other aspects of the plan involved the use of credit, with the President and the Federal Reserve Board moving to restrict unsecured loans by consumers and bank-to-bank loans, and energy, with the President imposing a conservation fee of about 10 cents a gallon on gasoline refined from imported petroleum.

Productivity, a long-term factor in inflation, has slowed sharply in the past 10 years and actually declined in 1979. To counter this development, the President said that he was asking his Commission on an Agenda for the 1980's for "recommendations for revitalizing our economy."

The proposal to cut the Federal budget drew an immediate objection from AFL–CIO President Lane Kirkland, who contended that the burden would fall most heavily on those already suffering most from inflation. Kirkland maintained that the new policies will do nothing to attack the "direct causes of inflation—the escalating costs of energy, housing, food, and medical care and the incredibly high interest rates that have a critical impact on all sectors of the economy."

Coal Commission issues final report

The final report of the President's Commission on Coal calls on the United Mine Workers and the Bituminous Coal Operators' Association to immediately begin negotiating on renewal of the coal contract which expires in March 1981. Both sides said they were pleased with the commission's final report which offers measures for improving labor-management relations, reducing U.S. dependence on oil, and for dealing with the continuing problem of coal-mine safety and the living conditions of miners.

Recalling that the last five contract settlements in the industry have been preceded by strikes, the commission attributed the strained labor-management relations in the industry to internal factors, such as dissension among leaders of the union and an influx of young, inexperienced workers. On the management side, the commission said that the BCOA's unity had been broken by a growing diversity of interest between underground and surface mining firms and between the traditional operators and some of the newer producers.

However, the commission concluded this portion of its report on an optimistic note, saying that the young supervisors and workers in the industry are maturing and gaining experience in mining—wildcat strikes have declined and that productivity appears to be improving—and citing the growing realization by labor and management of their mutual role in attaining a healthy, stable industry.

In addition to calling for an early start on collective bargaining, the commission also recommended that the union's leaders continue their efforts to stop wildcat strikes and "stranger picketing" and that the growing body of arbitration awards regarding these activities be respected; that labor and management continue their efforts to improve productivity, and that they expand training in this area, as well as in job safety, grievance handling, and labor-management relations; and that the parties establish a joint committee, headed by a neutral

---

"Developments in Industrial Relations" is prepared by George Ruben and other members of the staff of the Division of Trends in Employee Compensation, Bureau of Labor Statistics, and is largely based on information from secondary sources.

person, for continuing action on issues of mutual concern.

The commission presented statistics showing that coal mining is the most hazardous major occupation and made four recommendations; (1) that labor and management accept the principle that there is no place in the industry for firms and employees who are not prepared to observe safe mining practices; (2) that the Mine Safety and Health Administration increase its inspection and enforcement activities in mines the commission finds to have accident and fatality rates consistently and substantially above national averages; (3) that the National Academy of Science, in cooperation with all interested parties, conduct an investigation of the factors that distinguish safe mines from unsafe mines; and (4) that the BCOA and the UMW continue the joint task force on safety that had been established in cooperation with the commission.

The commission found that miners' living conditions have improved in the last generation to the point of being "more closely in line with mainstream America." However, the commission advocated three actions to counter problems resulting from expansion of the industry: that coal companies and other large landholders in areas lacking adequate housing make available parcels of land for new housing; that coal companies retain part of their working capital in local lending institutions committed to improving local housing; and that regional government subdivisions, in cooperation with mine owners and employees, identify and obtain public sector funding to spur the building of homes, roads, and utilities, and that the power of eminent domain be used to acquire land otherwise not available for housing.

The increasing price of petroleum, military developments that threaten the security of world supplies of petroleum, and doubts about public acceptance of nuclear power caused the commission to broaden its inquiry beyond the original mandate "to report on ways to improve labor-management relations." Under this broadened mandate, the commission presented principles it said must govern the Nation's efforts to meet the energy shortage. Specific recommendations that conformed with the principles included: use of coal to replace oil and natural gas in generating electricity and in industrial boilers; use of natural gas to replace oil in home and commercial heating and in industrial uses where coal is impractical; and reserving oil primarily for petrochemical products and transportations uses.

The President's Commission on Coal was established in 1978. It was chaired by John D. Rockefeller IV, Governor of West Virginia. Other members were Jesse F. Core, Adjunct Professor of Mining Engineering, Pennsylvania State University; Marvin Friedman, Vice President, Ruttenberg, Friedman, Kilgallon, Gutchess and Associates, Inc., Washington, D.C.; W. Dewey Presley, Director and Chairman of the Executive Committee, First International Bancshares, Inc., Dallas, Tex.; and W. Willard Wirtz, Wirtz and Lapointe, Washington, D.C.

In a related development in the industry, members of the BCOA ratified structural changes that will put the largest operators in control of the coming negotiations with the UMW. The change in bargaining approach was expected to induce U.S. Steel Corp. to withdraw its threat to leave the BCOA. The change also resulted in the return of Consolidation Coal Co., the Nation's second largest producer, which had quit the BCOA in May 1979 because it believed there was excessive disunity in the ranks of the operators—particularly the smaller ones—during the 1978 bargaining.

Under the restructuring, the executives of the nine largest companies are in charge of the bargaining, with the three-member bargaining team to consist of representatives of U.S. Steel and the largest producers, Peabody Coal Co. and Consolidation Coal Co. The smaller companies opposed the restructuring, but their proposal to temper the change drew only 22 percent of the votes.

Firestone to close six plants

The problems of the tire manufacturing industry were reflected in Firestone Tire and Rubber Co.'s announcement that it plans to close six plants. Company chairman and chief executive officer Richard A. Riley said the closings were necessary "to meet changing market conditions" and would eliminate "unneeded capacity that has been used mainly for the production of bias-ply tires."

Another Firestone official said that the domestic industry has been running at only 65 to 75 percent of capacity and projected demand is slowing. Among the reasons for lower production are increased use of radial tires, which wear longer than bias-ply tires; decreased driving due to increasing fuel costs; elimination of spare tires on some cars; and increased imports.

United Rubber Workers president Peter Bommarito said that he was shocked that the company would take "such drastic action" without first asking the union for help in keeping the plants open. Bommarito declared that the U.S. automobile manufacturers had aggravated the tire industry's problems by failing to produce fuel-efficient cars, thus losing sales to foreign companies. He indicated that the union would initiate immediate discussions with Firestone on ways to keep the plants open. Under the union's 1979 contracts, tire manufacturers are required to give the union 6 months' notice of plant closings.

According to a Firestone official, the severance pay, pension, and other costs of the shutdowns will total about $82 million, but will be partly offset by $33 million from the sale of inventories. The company reported a loss of $13.8 million for the 3 months ended January 31, compared with a profit of $34.8 million for the same period a year earlier.

The plants involved are in Salinas and Los Angeles, Calif., Dayton, Barbeton, and Akron, Ohio, and Pottstown, Pa. A total of 7,265 active employees will be affected, in addition to the 1,575 already on layoff. According to the union, this will bring to 19,200 the number of jobs lost in the industry since 1975. In January, Uniroyal, Inc., announced plans to close two of its five plants, which is expected to result in a loss of 3,300 jobs. In 1979, Mansfield Tire and Rubber Co. declared bankruptcy.

In a separate announcement, Firestone offered its 69,500 employees and retirees $100 if they buy a new domestic automobile in April. The company said such purchases will aid the automobile and rubber industries, as well as the general economy.

Large oil refineries negotiate pattern contract

The round of bargaining in petroleum refining moved rapidly towards a close, as the first of the major companies settled with the Oil, Chemical and Atomic Workers, ending an 11-week strike and setting a pattern for bargaining in the industry. The two similar accords were with Gulf Oil Corp. and Cities Service Co. The union had settled earlier with some small refineries on the package it had been seeking, but the major companies had balked at some demands. (See *Monthly Labor Review*, April 1980, p. 63.)

Gulf and Cities Service agreed to new 2-year contracts, while the earlier settlements provided for wage and benefit improvements during the final year of the existing 2-year contracts. Bargaining at all companies was conducted under reopening provisions of the existing contracts, negotiated in 1979.

The 1980 Gulf settlement provided for a wage increase of 5 percent plus 52 cents an hour, effective immediately, and a 10.5-percent increase in January 1981. The immediate increase included the 5-percent deferred raise already scheduled for that date under the 1979 settlement.

Under the Gulf settlement, the company's monthly payment to the health-care plan will be increased by $18.50 for family coverage and by $6 for single employees, effective immediately, and by $18 and $6 in January 1981. This will bring Gulf's obligation to $120.50 monthly for family coverage and $47 for single employees. However, employees will be required to pay any increase in the premium in excess of Gulf's obligation. A dental plan also was established, with Gulf paying $15.50 a month for family coverage and $4 for single coverage. The agreement also provided for a sixth week of paid vacation after 30 years of service.

Union president Robert Goss expressed "disappointment" that the oil workers had not won the company-paid health-care plan they had been seeking, but, "We just can't compete with the raw power of the multinational companies." One factor that definitely strengthened the companies' bargaining position is that the refineries are highly automated and can be operated by management employees during a walkout.

New contracts for glass container workers

Owens-Illinois, Inc., and the Glass Bottle Blowers negotiated 3-year contracts that set a pattern for several other companies in the glass container industry. The bargaining round involved a total of 77,000 workers, including 12,000 at Owens-Illinois, the largest firm.

The three separate, but essentially identical, Owens-Illinois accords covered production and related workers at 17 plants in the East, production and related employees at seven Western plants, and automatic machine operators at all plants. The agreements provide for a 68-cent general wage increase on the April 1 termination date of existing contracts and 55 cents on April 1 of 1981 and 1982. In addition, the increment between job grades was increased by an amount ranging from 10 cents an hour for employees in the lowest pay grade to no change for those in the highest grade. Production and maintenance workers in the Eastern plants received additional 2-, 1-, and 1-cent general increases on the respective dates to reduce a wage differential with the other employees. Other wage terms at all plants include an escalator clause that provides for adjustments in April of 1981 and 1982 if the Consumer Price Index rises more than 9 percent during the preceding 12 months. Adjustments will be at the rate of 1 cent for each 0.5-point increase in the index.

Shift differentials were increased by 3 cents an hour, to 20 cents for the afternoon shift and 24 cents for the night shift. Vacation pay was increased for employees with 22 to 25 years of service and all employees will receive an additional paid holiday. The monthly pension rate for each year of service was increased by $3 for employees in the lowest pay grades and by $2 for those in the highest, bringing the range to $14–$16. The benefit rate also was increased to a minimum $9 for current retirees, which affected employees who had retired before 1971 at $6.25 or $7 rates.

Life insurance coverage was increased by $3,000, bringing the new range to $13,000–$15,000, varying by job grade. The weekly sickness and accident benefit was increased by $30; and the maximum lifetime orthodontic benefit was increased to $1,000 per individual (formerly $750).

The companies that have settled on terms similar to Owens-Illinois include Brockway Glass Co., Thatcher Glass Manufacturing Co., Kerr Glass Manufacturing Co., Midland Glass Co., and Anchor Hocking Glass Corp.

Sugar companies settle

The International Longshoremen's and Warehousemen's Union and 12 Hawaiian sugar companies agreed to 2-year contracts that provided for February 1, 1980, and 1981 wage increases ranging from 55 cents an hour for employees in the lowest pay grade to 75 cents for those in the highest. After the 1981 increases, rates will range from $6.09 to $8.625 an hour. The same increase will apply at two "distressed" plantations that also settled—Maunakea Sugar Co. and Holo Coast Processing Co.—but will be accomplished in four steps instead of two.

Other provisions at all 14 plantations include a 10th annual paid holiday; increases in shift premiums; industrywide standardization of some job classifications; and an optional family-enrollment dental plan to replace the current plan that covers children only.

Eastern's flight attendants get new contract

Eastern Airlines and the Transport Workers negotiated a 3-year contract for flight attendants that provides for a 6-percent pay increase retroactive to April 1979, 2.5 percent retroactive to October 1979, 4 percent in May and December 1980, 5 percent in July 1981, and 6 percent in January 1982. The 5,500 employees also will receive automatic wage escalator adjustments in January of 1981 and 1982 of $1 a month for each 0.3-point movement in the Consumer Price Index. "Over-water-pay" was increased to $1.50 an hour (formerly $1.05), the "away-from-base" allowance was increased to $1.25 an hour (formerly 90 cents), and a pay step was added for employees with 13 years of service.

The minimum pension rate was increased to $24 a month for each year of service, and there is a provision for returning the contributions employees made before the plan became fully company-financed in 1977.

Eastern's variable earnings plan was continued. Under this plan, which was established in 1977 for the flight attendants and certain other employees, 3.5 percent of wages is withheld from paychecks but is returned to employees at yearend if the company's annual profit amounts to 2 percent of sales. If the profit is more than 2 percent, employees receive the full 3.5 percent and an additional amount up to 3.5 percent. If the profit is less than 2 percent, employees receive part of the withheld amount.

Honeywell employees reopen contract, get raises

About 8,700 Honeywell, Inc. employees in Minneapolis, Minn., were covered by a 2-year settlement with Local 1145 of the Teamsters. The new contract, negotiated under a reopening provision, was effective immediately, superseding the final year of the existing 3-year agreement.

The settlement provided for wage increases of 13 percent immediately and 11 percent in February 1981. There was no provision for a wage escalator clause. Company officials said they agreed to the relatively large set wage increases—rather than smaller increases and an escalator clause—because an escalator clause makes it more difficult to predict labor costs. Vice President Charles Brown said that a wage escalator clause that provides for cents-per-hour pay adjustments tends to be less beneficial to skilled employees because it reduces their percentage pay differential over less skilled workers.

The vacation schedule was increased by one day in the year in which employees attain 2, 5, 7, 10, 13, 16, and 22 years of service, and the maximum was increased to 30 days after 30 years, formerly 25 days after 24 years. There also were some improvements in insurance benefits. The separate 4-year pension contract provided for raising the benefit rate for future retirees to $18 a month for each year of credited service (formerly $12). Benefit rates for current retirees were increased to $14 (formerly $12), or to $12 (formerly $7–$10), depending on the date of retirement.

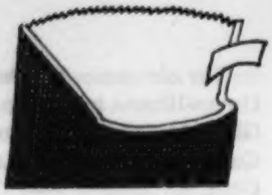
Minority attorneys at Justice charge bias

Attorneys employed by the U.S. Department of Justice filed an administrative complaint charging that the agency discriminates against minorities in hiring, training, and promotion. The formal complaint was filed by leaders of the group, the Racial and Ethnic Minority Attorneys Caucus, on behalf of about 150 attorneys after unsuccessful negotiations on the issue. The attorneys make up about 8 percent of all attorneys within the six units of the agency covered by the complaint.

Specifically, the complaint asserted that the units failed to hire or promote members of minority groups in adequate numbers; denied them equal access to training and the most interesting cases; and evaluated job performance in a manner that resulted in a disproportionate share of pay awards going to nonminority attorneys.

The 2 years of negotiations prior to the filing reportedly were not successful because the leaders of the caucus had been seeking remedies beyond those in the agency's affirmative action plan. ☐

Book Reviews



The unemployed tell their story

Not Working: An Oral History of the Unemployed. By Harry Maurer. New York, Holt, Rinehart and Winston, 1980. 297 pp. $12.95.

Not Working is an important book about unemployment in American society. Unlike the typical book on the subject, it focuses on people rather than statistics. It is about unemployed executives and clerks, engineers and auto workers, college professors and high school dropouts. In his oral history of unemployment, Harry Maurer has done for the unemployed what Studs Terkel did for the employed. And he has done it well.

In 1976, Maurer spent several months traveling around the United States interviewing the unemployed. This book is the fruit of that effort and many of his more than four dozen portraits of the unemployed are not easily forgotten. A gifted interviewer, Maurer managed to get a wide spectrum of America's jobless to talk freely and frankly about themselves and what it's like to be jobless in a work-oriented society.

The book vividly illustrates that unemployment does not just hit blacks or those without skills or education. Even for those who seem to have "made it," employment security is often tenuous. Nor does education alone guarantee a place in today's job market. Some of the most memorable interviews are with "high level" or "professional" workers.

There is, for example, Grace Keaton, fired without warning from a high-level job in a New York publishing house after 12 years of service. No one will hire her for a high-level job—nor will they consider her for a lower level job.

There is particularly good coverage of the plight of the middle-aged jobless professional, a problem that receives less than its share of public concern. Take Martin Penn, a 57-year-old scholar with a Ph. D. in anthropology, the victim of a layoff from a prestigious think-tank beset with shrinking government contracts. Lowering his sights after years of futile search for an appropriate job, and almost prepared to deny he has a Ph. D., Penn wonders what's wrong with the country when a person has to be ashamed of having an education.

Well-educated young people often find no demand for their labor or are forced into unskilled jobs. Kristen Jacobs, a recent and disillusioned liberal arts graduate of the University of Michigan, competes with 300 other applicants for a $3.60-an-hour job.

The author paints just as clear a picture of what it's like for those who have always been on the bottom of the job ladder. Minority youths are not dismal statistics. They appear as people who are being assaulted and destroyed by unemployment—or by the low wages and unsteady jobs that may be available from time to time.

Some ghetto teenagers interviewed by Maurer are receiving training. But the problems are shown to persist beyond the teens. Maurer's young adult minority jobless scarcely fit the stereotype of the jobless and poor as lazy. Ken Dutton, a 21-year-old black veteran in Seattle, Wash., camps out from 10 p.m. in the desperate hope that he will be one of the lucky few to be interviewed by Alcoa the next morning. Micky Eldridge, a 23-year-old black man in the South—out of work for a year—survives by collecting discarded coke bottles and selling them for 5 cents apiece. Eddie Varga, a 24-year-old Los Angeles Chicano—graduate of a 2-year technical college—lives on unemployment insurance and hopes for the miracle of a $3-an-hour job. While Willie Hawkins, a 23-year-old Birmingham black with hypertension, receives a call from an auto company for a same-day interview for a once-in-a-lifetime chance at a decent-paying job. In a frantic attempt to bring his blood pressure down quickly enough to pass the physical, he donates blood and takes large doses of Epsom salts just prior to the interview.

Maurer's people are real, with all the strengths and frailties of human beings. He has not canonized them, nor masked their shortcomings. Some are not eligible for unemployment benefits; others are too humiliated to take unemployment benefits; still others take them to survive, despite injured pride; some take them as a form of revenge; and a few abuse the system. For another few, all middle class, unemployment brings positive benefits. A teacher laid off during the New York fiscal crisis, for example, realizes that she had become a prisoner of a detested job. For her, being fired becomes a form of freedom.

This book also points to other problems. For in talking about not working, the jobless are also talking about working. The extent to which alienation and purposelessness exist in the workplace is hotly disputed. But among those in *Not Working*, it is commonplace.

The book also provides very useful insights into subtle aspects of the labor market, especially the secondary labor market. Like Elliot Liebow's *Tally,* we hear about the secondary labor market from those forced to spend their lives in it.

In *Unemployment in History,* John A. Garraty claims that, unlike the jobless of previous eras, today's unemployed are not plagued by psychological torment and feelings of self-blame. But Harry Maurer finds the opposite to be true. "What astonished me—more than any other discovery in the course of writing this book—was the degree to which unemployed people blame themselves." Even those made jobless by mass layoffs and other events clearly beyond their control tended to blame themselves. Unemployment, it turns out, means for many people psychological devastation, feelings of worthlessness, leisure turned to emptiness. Maurer's findings are consistent with the more structured research of Robert McKersie of Cornell University, who studied job loss among laid-off New York State civil servants, and M. Harvey Brenner's well-known study of the social costs of unemployment for the Joint Economic Committee.

If self-torment and guilt are as prevalent among all of the unemployed as among Maurer's group, the often observed lack of political protests by the jobless becomes more comprehensible. Self-blame effectively depoliticizes the victims of unemployment. The author feels that the jobless would do better to shift their attention to those who so willingly and unconcernedly want to increase unemployment.

There is, of course, no way of knowing just how representative Maurer's interviewees are of all the unemployed. He met the jobless in a variety of ways: some through organizational contacts; others directly in unemployment offices. Only a minority of the latter agreed to be interviewed. Were those who declined to be interviewed full of more self-blame than the others? Or less? Were they better off? Or worse off? Social scientists who want the answers to those questions will have to pick up where Maurer left off.

Some of Maurer's unemployed were hard hit by the last recession. In 1976, unemployment still averaged 7.7 percent. Though many ultimately may have found jobs, their scars are apt to remain. As Jim Hughes, a jobless Indiana Republican expressed it, "I'm always gonna look back on this and say, 'Hey, I've been through it. I know what it's like.' It's been rough. Human damage, you might say."

The unemployed deserve better. And there are still six million official jobless. So Harry Maurer's humanistic book should be of interest not only to economists, psychologists, sociologists, and others in the academic world but should be read by all who are concerned with current talk of increasing unemployment as a weapon against inflation. The Humphrey-Hawkins Full Employment and Balanced Growth Act (Public Law 95-523) declares among other things that it is the continuing policy and responsibility of the Federal Government to "promote full employment." The act also recognizes the problem of inflation but, based on considerable evidence, it rejects the idea of an inevitable inverse relationship between unemployment and inflation. Thus, it aims to reduce inflation while pursuing full employment. By showing what unemployment does to those forced to bear its costs, *Not Working* may help to focus national attention on the need to implement that law with vigor.

Working less and enjoying it more

Job Sharing: A New Pattern for Quality of Work and Life. By Gretl S. Meier. Kalamazoo, Mich., W. E. Upjohn Institute for Employment Research, 1979. 187 pp. $4.50.

Job sharing (commonly defined as two workers or more sharing one full-time job) is designed to increase both the number and quality of part-time jobs. This new type of schedule is part of a trend toward more flexible work arrangements. It responds specifically, however, to two recent phenomena. One is the increasing reluctance of many workers to work below their skill level in exchange for shorter hours. The second is a slowdown in the long-term growth in the supply of traditional part-time jobs.

Gretl S. Meier's excellent book covers recent experiences and trends in job sharing. It examines different types of arrangements, the advantages, disadvantages, and problems of job sharing for both employees and employers, and emerging issues. Her own survey of about 240 job sharers and more than 80 lengthy interviews with job sharers and their supervisors furnish the basic materials for the book.

To fulfill the author's criteria for job sharing, the sharing must be voluntary, involve the deliberate conversion of a full-time position, and provide fringe benefits (although not all the arrangements described meet the second and third requirements). Some sharers work in close partnership—pooling resources and sharing decisions and responsibility for the whole job; others work more or less independently. In some instances, job sharers are husband and wife; in others they never meet, communicating by phone or note only. The many variations on the general theme have given rise to such special terms as split, paired, twinned, and tandem jobs. (Work-sharing, which is undertaken to avoid layoffs, is an altogether different phenomenon.)

Sharing a full-time job does provide some sharers with more highly skilled work than would most traditional part-time jobs. The survey group includes, for example, managers, teachers, counselors, researchers, and physicians. (However, in the large majority of cases the combined earnings of both partners did not exceed the ceiling on which the salary of one worker would be taxed under social security.) Most job sharers surveyed received such fringe benefits as vacations, holidays, and sick leave, prorated in many cases on the basis of hours. Health benefits varied widely, with some sharers receiving full coverage and others excluded.

The greatest reward perceived by job sharers is the opportunity to balance worklife with the rest of life. "Work is central in the lives of job sharers, but not the sole criterion for identity."

Meier acknowledges that at present job sharers represent an "infinitesimal proportion of all jobholders" and that "until a larger, more varied pool . . . exists, it will be difficult to assess the benefits as well as the costs of the new arrangements—either to the organization or the individuals." She urges, however, that choices in implementing new work schedules not rest solely on narrow cost-benefit calculations, but take into account the relation of work to the totality of life. Whatever the outcome for this particular work schedule, recent increases in the number of both working couples and single-parent families and growing concerns for employment opportunities for handicapped workers make the upgrading of part-time work options an important objective.

Quick introduction to our way of life

Vietnamese Americans: Patterns of Resettlement and Socioeconomic Adaptation in the U.S. By Darrel Montero. Boulder, Colo., Westview Press, 1979. 218 pp., bibliography. $17.50.

Refugee movements are by their very nature sudden, disruptive, often traumatic events. As such, receiving countries typically face a complex task in successfully resettling large numbers of homeless people without some strain on the domestic social fabric. Seldom is there adequate time or resources to gather detailed information on the newcomers' backgrounds, initial adjustment difficulties on arrival, and subsequent socioeconomic progress, despite the potential value of such information for better accommodating future refugees.

In the last 5 years, more than 170,000 Indochinese have fled to the United States, the largest single refugee group to enter this country in such a brief period. Nevertheless, the U.S. Department of Health, Education, and Welfare has managed to produce a rich longitudinal data source on them, and this volume, by Darrel Montero, gives a valuable first look at its main findings. In a book addressed primarily to immigration specialists, Montero sets himself two objectives: first, to provide a systematic description and analysis of the survey's methodology and central results; then, to construct a model which integrates these results with existing knowledge on the resettlement and employment patterns of earlier immigrants.

The book opens with a chapter on Vietnam, briefly scanning its history from the 10th century B.C. to the U.S. defeat in April 1975. One cannot help thinking that the author's desire to deepen our understanding of the refugees' backgrounds, motivations, and expectations would have been better served had he focused on the evolution and operation of social, educational, and labor market structures, particularly in the urban areas whence most refugees came. Instead, he presents a largely political survey of premodern Vietnam, devoting a single page to the two decades since the mid-1950's which most shaped the refugees' lives.

In the following chapter, however, Montero gives a lucid description of the resettlement process in the United States and initial adjustment problems. After an abrupt, ill-prepared departure, the refugee family was taken to a relocation center at Camp Pendleton, Calif., or 1 of 3 other military bases. To minimize the financial burden on war-weary taxpayers, the Federal Interagency Task Force in charge of resettlement adopted a policy of moving its charges out of the camps quickly and scattering them across the country in the care of sponsoring groups and families. This practice isolated the new arrivals from their countrymen and impeded the formation of the sort of indigenous ethnic communities which new immigrant groups have traditionally relied on for social, economic, and emotional support.

But, Montero argues, the relocation centers and private sponsors helped acclimate the Vietnamese and prepared them for eventual self-sufficiency. Food, shelter, medical care, English language courses, and vocational training were freely supplied in the camps and the subsequent sponsorships provided not only economic security, but closer contact with American society and culture and assistance in locating employment. The refugees' demographic characteristics count as additional advantages. Drawing on Immigration and Naturalization Service data, the author notes that most refugees are young (nine-tenths under age 45), well educated, from relatively affluent urban families, and among their homeland's social and occupational elite.

How have they fared in the American labor market? To trace the refugees' socioeconomic adaptation, Montero presents the salient findings of five waves of national survey interviews conducted under the auspices of the Department of Health, Education, and Welfare between July 1975 and August 1977. The profile which emerges is one of "substantial progress" in which "the Vietnamese are moving steadily toward economic self-sufficiency." Employment rates are high for both men and women, more than 80 percent are working full time by Survey V, and income has steadily risen to a median annual level of $9,600 in 1977.

At the same time, however, the refugees have suffered marked downward occupational mobility. One-third of household heads were professional workers in Vietnam, but fewer than 1 in 5 could find similar employment in the United States. Former managers and administrators encountered even greater difficulties. This pattern is in striking accord with that found for other immigrant groups in recent studies by Chiswick, North, and the reviewer.

To place the Vietnamese experience in a wider sociohistorical context, the author concludes by advancing what he dubs a model of "Spontaneous International Migration." Comparisons are drawn between the route taken by earlier Japanese and Chinese immigrants —from their homelands, to ethnic enclaves, thence toward assimilation—and the ongoing movement of the Vietnamese. Aided by their "anticipatory socialization" among American troops and employers in Vietnam as well as further preparation in the camps and sponsorships, the refugees will, it is predicted, have less need for ethnic concentrations and assimilate more rapidly than other immigrants. This is less a genuine theoretical model than a rough descriptive outline. Furthermore, comparisons with other refugee groups, like the Cubans who also had considerable premigration contact with Americans but remain concentrated in ethnic enclaves, would seem more relevant.

Nonetheless, *Vietnamese Americans* serves a clear need for more precise panel data on recent immigrant cohorts; in fact, more than half of its pages consist of statistical tables. Until the Department of Health, Education, and Welfare gives researchers access to the survey's original data tapes, this book will be a unique source of detailed information for immigration scholars.

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics. A brief introduction to each group of tables provides definitions, notes on the data, sources, and other material usually found in footnotes.

Readers who need additional information are invited to consult the BLS regional offices listed on the inside front cover of this issue of the *Review*. Some general notes applicable to several series are given below.

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might otherwise mask short-term movements of the statistical series. Tables containing these data are identified as "seasonally adjusted." Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years. For a technical discussion of the method used to make seasonal adjustments, see "Appendix A. The BLS Seasonal Factor Method," *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), pp. 272–78, and *X-11 Variant of the Census Method II Seasonal Adjustment Program*, Technical Paper No. 15 (Bureau of the Census, 1967). Seasonally adjusted labor force data in tables 2–7 were last revised in the February 1980 issue of the *Review* to reflect the preceding year's experience. Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X-11/ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada Catalogue No. 12-564E, September 1979).

The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. Revisions of historical data continue to be made only at the end of each calendar year. Annual revision of the seasonally adjusted payroll data in tables 11, 13, 16, and 18 was last introduced in the November 1979 issue of the *Review*. New seasonal factors for productivity data in tables 33 and 34 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The resulting values are described as "real," "constant," or "1967" dollars.

Availability of information. Data that supplement the tables in this section are published by the Bureau of Labor Statistics in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule given below. The *Handbook of Labor Statistics 1978*, Bulletin 2000, provides more detailed data and greater historical coverage for most of the statistical series presented in the *Monthly Labor Review*. More information from the household and establishment surveys is provided in *Employment and Earnings*, a monthly publication of the Bureau, and in two comprehensive data books issued annually—*Employment and Earnings, United States* and *Employment and Earnings, States and Areas*. More detailed information on wages and other aspects of collective bargaining appears in the monthly periodical, *Current Wage Developments*. More detailed price information is published each month in the periodicals, the *CPI Detailed Report* and *Producer Prices and Price Indexes*.

Symbols

p = preliminary. To improve the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.

Schedule of release dates for major BLS statistical series

Title and frequency (monthly except where indicated)	Release date	Period covered	Release date	Period covered	MLR table number
Employment situation	May 2	April	June 6	May	1 - 11
Producer Price Indexes	May 9	April	June 6	May	26 - 30
Consumer Price Index	May 23	April	June 24	May	22 - 25
Real earnings	May 23	April	June 24	May	14 - 20
Productivity and costs (quarterly):					
Nonfinancial corporations	May 28	1st quarter	....	....	31 - 34
Work stoppages	May 28	April	June 30	May	37
Labor turnover in manufacturing	May 30	April	June 30	May	12 - 13

EMPLOYMENT DATA FROM THE HOUSEHOLD SURVEY

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 65,000 households beginning in January 1980, selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons are (1) those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population; the **total labor force** includes military personnel. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons retired, those engaged in their own housework, those not working while attending school, those unable to work because of longterm illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy.

Full-time workers are those employed at least 35 hours a week; **part-time workers** are those who work fewer hours. Workers on part-time schedules for economic reasons (such as slack work, terminating or starting a job during the week, material shortages, or inability to find full-time work) are among those counted as being on full-time status, under the assumption that they would be working full time if conditions permitted. The survey classifies unemployed persons in full-time or part-time status by their reported preferences for full-time or part-time work.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data presented in table 1. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 2–7 are seasonally adjusted, based on the seasonal experience through December 1979.

1. Employment status of the noninstitutional population, 16 years and over, selected years, 1950–79

[Numbers in thousands]

Year	Total noninstitutional population	Total labor force		Civilian labor force						Not in labor force

NOTE: The monthly data in these tables have been revised to reflect seasonal experience through 1979.

EMPLOYMENT, HOURS, AND EARNINGS DATA FROM ESTABLISHMENT SURVEYS

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by 162,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

LABOR TURNOVER DATA in this section are compiled from personnel records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies. A sample of 40,000 establishments represents all industries in the manufacturing and mining sectors of the economy.

Definitions

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 14–20 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in transportation and public utilities, in wholesale and retail trade, in finance, insurance, and real estate, and in service industries. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to eliminate the effects of price change. The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries. **Spendable earnings** are earnings from which estimated social security and Federal income taxes have been deducted. The Bureau of Labor Statistics computes spendable earnings from gross weekly earnings for only two illustrative cases: (1) a worker with no dependents and (2) a married worker with three dependents.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

Labor turnover is the movement of all wage and salary workers from one employment status to another. **Accession rates** indicate the average number of persons added to a payroll in a given period per 100 employees; **separation rates** indicate the average number dropped from a payroll per 100 employees. Although month-to-month changes in employment can be calculated from the labor turnover data, the results are not comparable with employment data from the employment and payroll survey. The labor turnover survey measures changes during the calendar month while the employment and payroll survey measures changes from midmonth to midmonth.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of September 1979 data, published in the November 1979 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Complete comparable historical unadjusted and seasonally adjusted data are published in a Supplement to Employment and Earnings (unadjusted data from April 1977 through June 1979 and seasonally adjusted data from January 1974 through June 1979) and in *Employment and Earnings, United States, 1909–78*, BLS Bulletin 1312–11 (for prior periods).

Data on recalls were shown for the first time in tables 12 and 13 in the January 1978 issue of the *Review*. For a detailed discussion of the recalls series, along with historical data, see "New Series on Recalls from the Labor Turnover Survey," *Employment and Earnings*, December 1977, pp. 10–19.

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20. See also *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976).

The formulas used to construct the spendable average weekly earnings series reflect the latest provisions of the Federal income tax and social security tax laws. For the spendable average weekly earnings formulas for the years 1978–80, see *Employment and Earnings*, March 1980, pp. 10–11. Real earnings data are adjusted using the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

NOTE: The earnings expressed in 1967 dollars have been adjusted for changes in price level as measured by the Bureau's Consumer Price Index for Urban Wage Earners and Clerical Workers.

These series are described in "The Spendable Earnings Series: A Technical Note on its Calculation," **Employment and Earnings and Monthly Report on the Labor Force,** February 1969, pp. 6-13. See also "Spendable Earnings Formulas, 1978-80," **Employment and Earnings,** March 1980, pp. 10-11.

UNEMPLOYMENT INSURANCE DATA

UNEMPLOYMENT INSURANCE DATA are compiled monthly by the Employment and Training Administration of the U.S. Department of Labor from records of State and Federal unemployment insurance claims filed and benefits paid. Railroad unemployment insurance data are prepared by the U.S. Railroad Retirement Board.

Definitions

Data for **all programs** represent an unduplicated count of insured unemployment under the State, Ex-Servicemen, and UCFE programs, and the Railroad Insurance Act.

Under both State and Federal unemployment insurance programs for civilian employees, insured workers must report the completion of at least 1 week of unemployment before they are defined as unemployed. Persons not covered by unemployment insurance (about one-third of the labor force) and those who have exhausted or not yet earned benefit rights are excluded from the scope of the survey. **Initial claims** are notices filed by persons in unemployment insurance programs to indicate they are out of work and wish to begin receiving compensation. A claimant who continued to be unemployed a full week is then counted in the insured unemployment figure. The **rate of insured unemployment** expresses the number of insured unemployed as a percent of the average insured employment in a 12-month period.

An **application** for benefits is filed by a railroad worker at the beginning of his first period of unemployment in a benefit year; no application is required for subsequent periods in the same year. **Number of payments** are payments made in 14-day registration periods. The **average amount of benefit payment** is an average for all compensable periods, not adjusted for recovery of overpayments or settlement of underpayments. However, **total benefits** paid have been adjusted.

21. Unemployment insurance and employment service operations

[All items except average benefits amounts are in thousands]

[1] Initial claims and State insured unemployment include data under the program for Puerto Rican sugarcane workers.

[2] Includes interstate claims for the Virgin Islands. Excludes transition claims under State programs.

[3] Excludes data on claims and payments made jointly with other programs.

[4] Includes the Virgin Islands. Excludes data on claims and payments made jointly with State programs.

[5] Cumulative total for fiscal year (October 1 - September 30).

NOTE: Data for Puerto Rico included. Dashes indicate data not available.

PRICE DATA

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Definitions

The **Consumer Price Index** is a monthly statistical measure of the average change in prices in a fixed market basket of goods and services. Effective with the January 1978 index, the Bureau of Labor Statistics began publishing CPI's for two groups of the population. One index, a new CPI for All Urban Consumers, covers 80 percent of the total noninstitutional population; and the other index, a revised CPI for Urban Wage Earners and Clerical Workers, covers about half the new index population. The All Urban Consumers index includes, in addition to wage earners and clerical workers, professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctor's and dentist's fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items is kept essentially unchanged between major revisions so that only price changes will be measured. Prices are collected from over 18,000 tenants, 24,000 retail establishments, and 18,000 housing units for property taxes in 85 urban areas across the country. All taxes directly associated with the purchase and use of items are included in the index. Because the CPI's are based on the expenditures of two population groups in 1972–73, they may not accurately reflect the experience of individual families and single persons with different buying habits.

Though the CPI is often called the "Cost-of-Living Index," it measures only price change, which is just one of several important factors affecting living costs. Area indexes do not measure differences in the level of prices among cities. They only measure the average change in prices for each area since the base period.

Producer Price Indexes measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes contains about 2,800 commodities and about 10,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The universe includes all commodities produced or imported for sale in commercial transactions in primary markets in the United States.

Producer Price Indexes can be organized by stage of processing or by commodity. The stage of processing structure organizes products by degree of fabrication (that is, finished goods, intermediate or semifinished goods, and crude materials). The commodity structure organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States, from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

In calculating Producer Price Indexes, price changes for the various commodities are averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage of processing groupings, commodity groupings, durability of product groupings, and a number of special composite groupings.

Price indexes for the output of selected SIC industries measure average price changes in commodities produced by particular industries, as defined in the *Standard Industrial Classification Manual 1972* (Washington, U.S. Office of Management and Budget, 1972). These indexes are derived from several price series, combined to match the economic activity of the specified industry and weighted by the value of shipments in the industry. They use data from comprehensive industrial censuses conducted by the U.S. Bureau of the Census and the U.S. Department of Agriculture.

Notes on the data

Beginning with the May 1978 issue of the *Review*, regional CPI's cross classified by population size, were introduced. These indexes will enable users in local areas for which an index is not published to get a better approximation of the CPI for their area by using the appropriate population size class measure for their region. The cross-classified indexes will be published bimonthly. (See table 24.)

For further details about the new and the revised indexes and a comparison of various aspects of these indexes with the old unrevised CPI, see *Facts About the Revised Consumer Price Index*, a pamphlet in the Consumer Price Index Revision 1978 series. See also *The Consumer Price Index: Concepts and Content Over the Years*. Report 517, revised edition (Bureau of Labor Statistics, May 1978).

For interarea comparisons of living costs at three hypothetical standards of living, see the family budget data published in the *Handbook of Labor Statistics, 1977*, Bulletin 1966 (Bureau of Labor Statistics, 1977), tables 122–133. Additional data and analysis on price changes are provided in the *CPI Detailed Report* and *Producer Prices and Price Indexes*, both monthly publications of the Bureau.

As of January 1976, the Wholesale Price Index (as it was then called) incorporated a revised weighting structure reflecting 1972 values of shipments. From January 1967 through December 1975, 1963 values of shipments were used as weights.

For a discussion of the general method of computing consumer, producer, and industry price indexes, see *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), chapters 13–15. See also John F. Early, "Improving the measurement of producer price change," *Monthly Labor Review*, April 1978, pp. 7–15. For industry prices, see also Bennett R. Moss, "Industry and Sector Price Indexes," *Monthly Labor Review*, August 1965, pp. 974–82.

[1] Prices for natural gas are lagged 1 month.

[2] Includes only domestic production.

[3] Most prices for refined petroleum products are lagged 1 month.

[4] Some prices for industrial chemicals are lagged 1 month.

[5] Data for November 1979 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

28. Producer Price Indexes, for special commodity groupings

[1967 = 100 unless otherwise specified]

Commodity grouping	Annual average 1978	1979										1980		
		Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.[1]	Dec.	Jan.	Feb.	Mar.
All commodities — less farm products	208.4	224.7	228.0	230.1	232.0	235.4	237.5	241.4	245.3	247.0	249.2	255.4	260.5	262.6
All foods	206.4	225.9	227.7	226.4	223.8	225.4	224.7	228.5	226.9	230.0	232.1	231.1	235.7	234.7
Processed foods	206.7	225.6	227.8	227.5	224.7	226.4	224.8	230.8	228.9	231.8	234.1	233.3	238.5	236.8
Industrial commodities less fuels	197.2	211.9	214.7	216.0	217.0	219.0	220.3	222.0	225.9	226.9	228.1	234.3	237.5	238.4
Selected textile mill products (Dec. 1975 = 100)	108.8	111.6	112.3	112.8	113.5	114.0	115.1	115.8	116.4	117.0	117.0	118.8	119.4	121.1
Hosiery	106.3	110.5	112.5	112.5	112.7	114.1	113.0	112.7	113.3	114.6	115.3	119.5	119.6	119.9
Underwear and nightwear	158.9	167.1	167.3	167.7	168.3	168.5	170.8	170.8	171.2	171.6	172.9	175.7	177.8	181.8
Chemicals and allied products, including synthetic rubber and manmade fibers and yarns	190.5	200.0	204.1	207.6	209.5	215.0	218.6	220.9	224.3	226.3	228.6	235.8	238.2	242.1
Pharmaceutical preparations	140.6	149.4	150.0	150.1	151.7	151.7	152.0	153.6	155.6	155.4	156.9	159.2	160.4	161.7
Lumber and wood products, excluding millwork and other wood products	298.3	323.7	326.4	325.1	321.7	325.3	333.9	341.0	337.3	323.3	310.3	308.6	314.0	312.2
Special metals and metal products	209.6	228.2	232.7	232.4	233.7	235.5	234.9	236.4	243.4	244.5	245.9	253.5	255.7	254.8

[2] Data for November 1979 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

PRODUCTIVITY DATA

Productivity data are compiled by the Bureau of Labor Statistics from establishment data and from estimates of compensation and output supplied by the U.S. Department of Commerce and the Federal Reserve Board.

Definitions

Output is the constant dollar gross domestic product produced in a given period. Indexes of **output per hour of labor input,** or labor productivity, measure the value of goods and services produced per hour of labor. **Compensation per hour** includes wages and salaries of employees plus employers' contributions for social insurance and private benefit plans. The data also include an estimate of wages, salaries, and supplementary payments for the self-employed, except for nonfinancial corporations, in which there are no self-employed. **Real compensation per hour** is compensation per hour adjusted by the Consumer Price Index for All Urban Consumers.

Unit labor cost measures the labor compensation cost required to produce one unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from the current dollar gross domestic product and dividing by output. In these tables, **Unit nonlabor costs** contain all the components of unit nonlabor payments except unit profits. **Unit profits** include corporate profits and inventory valuation adjustments per unit of output.

The **implicit price deflator** is derived by dividing the current dollar estimate of gross product by the constant dollar estimate, making the deflator, in effect, a price index for gross product of the sector reported.

The use of the term "man-hours" to identify the labor component of productivity and costs, in tables 31 through 34, has been discontinued. **Hours of all persons** is now used to describe the labor input of payroll workers, self-employed persons, and unpaid family workers. **Output per all-employee hour** is now used to describe labor productivity in nonfinancial corporations where there are no self-employed.

Notes on the data

In the private business sector and the nonfarm business sector, the basis for the output measure employed in the computation of output per hour is Gross Domestic Product rather than Gross National Product. Computation of hours includes estimates of nonfarm and farm proprietor hours.

Output data are supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are from the Bureau of Economic Analysis and the Bureau of Labor Statistics.

Beginning with the September 1976 issue of the *Review*, tables 31–34 were revised to reflect changeover to the new series—private business sector and nonfarm business sector—which differ from the previously published total private economy and nonfarm sector in that output imputed for owner-occupied dwellings and the household and institutions sectors, as well as the statistical discrepancy, are omitted. For a detailed explanation, see J. R. Norsworthy and L. J. Fulco, "New sector definitions for productivity series," *Monthly Labor Review*, October 1976, pages 40–42.

31. Indexes of productivity and related data, selected years, 1950–79

LABOR-MANAGEMENT DATA

MAJOR COLLECTIVE BARGAINING DATA are obtained from contracts on file at the Bureau of Labor Statistics, direct contact with the parties, and from secondary sources. Additional detail is published in *Current Wage Developments*, a monthly periodical of the Bureau. Data on work stoppages are based on confidential responses to questionnaires mailed by the Bureau of Labor Statistics to parties involved in work stoppages. Stoppages initially come to the attention of the Bureau from reports of Federal and State mediation agencies, newspapers, and union and industry publications.

Definitions

Data on wage changes apply to private nonfarm industry agreements covering 1,000 workers or more. Data on wage and benefit changes *combined* apply only to those agreements covering 5,000 workers or more. **First-year wage settlements** refer to pay changes going into effect within the first 12 months after the effective date of the agreement. **Changes over the life of the agreement** refer to total agreed upon settlements (exclusive of potential cost-of-living escalator adjustments) expressed at an average annual rate. **Wage-rate changes** are expressed as a percent of straight-time hourly earnings, while **wage and benefit changes** are expressed as a percent of total compensation.

Effective wage-rate adjustments going into effect in major bargaining units measure changes actually placed into effect during the reference period, whether the result of a newly negotiated increase, a deferred increase negotiated in an earlier year, or as a result of a cost-of-living escalator adjustment. Average adjustments are affected by workers receiving no adjustment, as well as by those receiving increases or decreases.

Work stoppages include all known strikes or lockouts involving six workers or more and lasting a full shift or longer. Data cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

35. Wage and benefit settlements in major collective bargaining units, 1975 to date

How to order BLS publications

PERIODICALS

Order from (and make checks payable to) Superintendent of Documents, Washington, D.C. 20402. For foreign subscriptions, add 25 percent.

Monthly Labor Review. The oldest and most authoritative government research journal in economics and the social sciences. Current statistics, analysis, developments in industrial relations, court decisions, book reviews. $18 a year, single copy, $2.50.

Employment and Earnings. A comprehensive monthly report on employment, hours, earnings, and labor turnover by industry, area, occupation, et cetera $22 a year, single copy $2.75.

Occupational Outlook Quarterly. A popular periodical designed to help high school students and guidance counselors assess career opportunities. $6 for four issues, single copy $1.75.

Current Wage Developments. A monthly report about collective bargaining settlements and unilateral management decisions about wages and benefits; statistical summaries. $12 a year, single copy $1.35.

Producer Prices and Price Indexes. A comprehensive monthly report on price movements of both farm and industrial commodities, by industry and stage of processing. $17 a year, single copy $2.25.

CPI Detailed Report. A monthly periodical featuring detailed data and charts on the Consumer Price Index. $15 a year, single copy $2.25.

PRESS RELEASES

The Bureau's statistical series are made available to news media through press releases issued in Washington. Many of the releases also are available to the public upon request. Write: Bureau of Labor Statistics, Washington, D.C. 20212.

Regional. Each of the Bureau's eight regional offices publishes reports and press releases dealing with regional data. Single copies available free from the issuing regional office.

BULLETINS AND HANDBOOKS

About 140 bulletins and handbooks published each year are for sale by regional offices of the Bureau of Labor Statistics (see inside front cover) and by the Superintendent of Documents, Washington, D.C. 20402. Make checks payable to the Superintendent of Documents. Among the bulletins and handbooks currently in print are these:

Occupational Outlook Handbook, 1978–79 Edition. Bulletin 1955. A useful resource supplying valuable assistance to all persons seeking satisfying and productive employment. $8, paperback; $11 hard cover.

BLS Handbook of Labor Statistics 1978. Bulletin 2000. A 604-page volume of historical data on the major BLS statistical series. $9.50.

Handbook of Methods. Bulletin 1910. Brief technical account of each major statistical program of the Bureau of Labor Statistics. $3.50.

BLS Measures of Compensation. Bulletin 1941. An introduction to the various measures of employee compensation; describes each series, the manner in which it is developed, its uses and limitations. $2.75.

Occupational Projections and Training Data. Bulletin 2020. Presents both general and detailed information on the relationship between occupational requirements and training needs. (Updates Bulletin 1918 published in 1976.) $3.25.

Technological Change and its Labor Impact in Five Energy Industries. Bulletin 2005. A 64-page study appraising major technological change and discussing the impact of these changes on productivity and occupations over the next 5 to 10 years. $2.40.

BLS Publications, 1972–77. Bulletin 1990. A numerical listing and subject index of bulletins and reports issued by the Bureau from 1972 through 1977, supplementing Bulletin 1749, covering 1886–1971. $1.80.

International Comparisons of Unemployment. Bulletin 1979. Brings together all of the Bureau's work on international unemployment comparisons. Describes the methods of adjusting foreign unemployment rates in 8 countries to U.S. concepts. $3.50.

Productivity Indexes for Selected Industries, 1979 Edition. Bulletin 2054. A 190-page report of indexes of output, employment, and employee hours in selected industries from 1954 to 1978. This edition contains measures for three industries previously not covered, as well as components of previously published measures in 10 industries. $5.50.

Profiles of Occupational Pay: A Chartbook. Bulletin 2037. A graphic illustration of some of the factors that affect workers' earnings. This three-part presentation looks at wage variations among and within occupations and portrays characteristics of high- and low-paying urban areas and manufacturing industries. $3.50.

REPORTS AND PAMPHLETS

Single copies available free from the BLS regional offices or from the Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

How the Government Measures Unemployment. Report 505. A concise report providing a background for appraising developments in the area of unemployment.

Directory of BLS Studies in Industrial Relations 1960–78. Report 550. A listing of studies prepared by the Division of Industrial Relations as part of the Bureau's regular program of data collection and analysis in the field of industrial relations.

The Bureau of Labor Statistics issues its 1979 edition of productivity indexes for selected industries.

Data on output per employee-hour, output, employee-hours, and employment are presented for the following industries:

- Iron mining
- Copper mining
- Coal mining
- Nonmetallic minerals
- Fluid milk
- Preserved fruits and vegetables
- Grain mill products
- Bakery products
- Sugar
- Candy and confectionery
- Malt beverages
- Bottled and canned soft drinks
- Tobacco products
- Hoisery
- Sawmills and planing mills
- Veneer and plywood
- Household furniture
- Paper, paperboard and pulp mills
- Folding paperboard boxes
- Corrugated and solid fiber boxes
- Synthetic fibers
- Pharmaceuticals
- Soaps and detergents
- Paints
- Petroleum refining
- Tires and inner tubes
- Footwear
- Glass containers
- Hydraulic cement
- Structural clay products
- Concrete products
- Ready-mixed concrete
- Steel
- Gray iron foundries
- Steel foundries
- Primary smelting and refining of copper, lead, and zinc
- Primary aluminum
- Copper rolling and drawing
- Aluminum rolling and drawing
- Metal cans
- Motors and generators
- Major household appliances
- Electric lamps
- Lighting fixtures
- Radio and TV receiving sets
- Motor vehicles and equipment
- Railroad transportation
- Intercity trucking
- Air transportation
- Petroleum pipelines
- Telephone communications
- Gas and electric utilities
- Retail food stores
- Franchised new car dealers
- Gasoline service stations
- Eating and drinking places
- Hotels and motels
- Laundry and cleaning services

The Monthly Labor Review is published by the Bureau of Labor Statistics of the U.S. Department of Labor. Communications on editorial matters should be addressed to the Editor-in-Chief,
Monthly Labor Review, Bureau of Labor Statistics,
Washington, D.C. 20212.
Phone: (202) 523-1327.

Subscription price per year—
$18 domestic; $22.50 foreign.
Single copy $2.50.
Subscription prices and distribution policies for the Monthly Labor Review (ISSN 0098-0818) and other Government publications are set by the Government Printing Office, an agency of the U.S. Congress. Send correspondence on circulation and subscription matters (including address changes) to:
Superintendent of Documents,
Government Printing Office,
Washington, D.C. 20402

Make checks payable to
Superintendent of Documents.

The Secretary of Labor has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through October 31, 1982. Second-class postage paid at Riverdale, MD., and at additional mailing offices.

Labor Month In Review

INDEXATION. The Consumer Price Index is widely used today for indexation; that is, to adjust payments to price changes. When indexation formulas devised by users bring unexpected results, the users sometimes blame the CPI. Commissioner of Labor Statistics Janet L. Norwood discussed this problem at a May 9 meeting of the Eastern Economic Association in Montreal, Canada. Excerpts:

CPI uses. The use of the CPI in escalation has become so popular in recent years, that a very large part of the population now has at least some of its income affected by the index. CPI escalation ranges from child support payments to welfare eligibility, from collective bargaining contracts to rental agreements, from pensions to social security payments, and from food stamps to school lunch programs. The CPI is also used to adjust presidential campaign funding and in several States for indexation of income tax brackets. Indeed, the tendency to add a CPI escalator to legislation has become so widespread that it is almost impossible for the Bureau of Labor Statistics to keep an up-to-date list of the uses of the CPI in indexation.

In general, the purpose of most escalator clauses has been to help those receiving payments maintain a base-period living standard by assuring that they recover the purchasing power which might be lost through price increases. The intent, therefore, is to permit people to purchase at today's prices the bundle of goods and services they purchased in the base period, thereby leaving them as well off as they were then.

BLS compiles and publishes two CPI's. The CPI-W represents the experience of urban wage earner and clerical families and covers approximately 40 percent of the total population. The CPI-U, a broader index which covers about 80 percent of the population, includes, in addition to the wage earners and clerical workers, such groups as salaried workers, the unemployed, the retired and the self-employed. Each index is published each month with a total—or All Items—Index and a large number of individual components as well as a series of special groupings. Both the CPI-U and the CPI-W are used in indexation.

Unexpected results. Use of the CPI to index payments sometimes produces results that were not anticipated at the time the escalation arrangements were made. As a result, situations arise from the *use* of the CPI as an escalator that result frequently in criticisms of the index itself. Those who, because of indexation, are required to make additional payments are often unprepared to do so, and they complain that the index is too high. Those who receive income that is indexed look at their own price experience, find that it is different from the average represented in the index, and insist that the index is too low. Finally, members of the Congress, suddenly faced with the need for increased outlays of government funds because they have provided for CPI escalation in many laws, begin to worry about the additional appropriations required for escalation and frequently transfer that concern into a criticism of the statistical series itself.

Causes for concern. In many of these cases, criticism of the CPI arises not because there are different views on the way inflation should be measured, but rather because those who have adopted an indexation policy based upon the use of the CPI do not like the results that it brings. Still others worry that, in a period of rising inflation, CPI escalation can, in fact, fuel the very inflation for which the indexing arrangements were designed to compensate, and that the CPI itself can become an engine of inflation. Difficulties faced by these groups are valid causes for concern; they also explain, I believe, some of the reasons for the recent public discussion and criticism of the CPI. While constructive criticism of price measurement techniques is both useful and sensible in a democratic society, we must be careful to separate complaints which quite properly deal with the techniques and concepts of price measurement from those which are based primarily upon the unexpected or unplanned results that arise from the use of the CPI in particular escalation formulas.

Information needed. Users of the index must become better informed about the benefits—and the dangers—of indexation so that they can make intelligent policy decisions before adopting it. They also need to have a better understanding of what the CPI is and how it measures price change. Measurement concepts and techniques appropriate for one purpose may not in fact be the best available for some other use. Interaction of producer, user, and policymaker is essential to the effective and timely development of statistical series that are relevant to the demands that are placed upon them. □

Employment gains of women by industry, 1968–78

In a decade, employment of women increased most rapidly in the service-producing sector where they already were concentrated; however, women are beginning to move into traditionally male-dominated jobs in the mining and construction industries

Howard Davis

Women filled more than half of the 18.5 million nonagricultural jobs created between 1968 and 1978. Although most of these jobs were in the rapidly expanding service sector, which traditionally employs a large share of women, female workers also made significant gains in several nontraditional industries—coal mining, construction, local and interurban transportation, and engineering and architectural services.

The proportion of women working or actively seeking work increased from 41.6 percent in 1968 to 50.1 percent in 1978. In contrast, the participation rate for men declined from 81.2 percent to 78.4 percent, in large part, because of reduced labor force participation among older men (age 45 and over). In fact, the civilian male labor force rose only 9 million during 1968–78, while total employment in nonagricultural industries increased by 18.5 million. Payroll data from the Bureau of Labor Statistics' establishment survey provide details of the flow of women into various industries. Establishment data do not yield information on earnings by sex and by industry;[1] however, the data do shed some light on the reason that earnings of women continue to lag behind those of men. As will be shown, those industries which have absorbed a large influx of women have been those with traditionally low hourly earnings.

Growth patterns, by sector

Although the proportion of women on nonagricultural payrolls increased from 35.9 percent in 1968 to 40.8 percent in 1978, almost all of the change occurred in the service-producing sector. (See table 1.) The proportion of women in the goods-producing sector edged off slightly. The 4.9-percentage points difference can be decomposed into a 5.6-point increase in female employment in the service-producing sector and a 0.7-point drop in the goods-producing sector.

One approach to use when tracing employment patterns of women is to separate the total change into that attributable to general employment growth or decline in the industry (constant-share) and that attributable to a change in the share of employment. The constant-share is calculated by multiplying the 1968 share of employment in each industry (or industry division) by the 1978 employment in that industry. In this manner, the number of women that would have been employed in an industry in 1978 can be determined, assuming their share of industry employment has not changed. The difference between the constant-share and the actual 1978 employment indicates how much female employment in 1978 has increased or decreased its share in an industry since 1968.

Allowing for the change in the distribution of employment between the goods- and service-producing sectors, but holding the proportion of female employment constant at 1968 levels, 32.3 million women, rather than 35.5 million, would have been employed in nonagricultural jobs in 1978. The increase then would have been 7.9 million women, rather than 10.9 million. (See table 2.)

About 73 percent of the 10.9-million increase in female workers can be ascribed to a constant-share increase and 27 percent to an increase in their employment share. Increased employment share accounted for 77.3 percent of the total female employment growth

---

Howard Davis is an economist in the Office of Employment Structure and Trends, Bureau of Labor Statistics.

in the goods-producing sector and 21.9 percent in the service-producing sector. An industry can have a significant increase in its proportion of female employment yet, if the constant-share growth is comparatively high, the increased proportion may not represent a large part of the total employment change. For example, the employment increase of women in the goods-producing sector attributable to an increase in share was 77.3 percent (compared with 21.9 percent in the service sector), but accounted for only 26.8 percent of the increase in all nonagricultural industries. Conversely, if the constant-share growth is negligible or negative, the increased proportion of employment may comprise a large part of the total difference in female employment.[2]

Constant-share growth differed markedly in the goods-producing and the service-producing sectors. Employment in the goods-producing sector expanded at a modest 0.8-percent annual rate; the service-producing sector had a 3.2-percent annual growth rate. The constant-share employment of women increased by 41 percent in the service-producing sector, compared to less than 4 percent in the goods-producing sector. Thus,

women experienced significant employment gains in the service-producing sector from both constant-share growth and proportional increases. Over the decade, the relative gains in female employment (the total change in female employment divided by the number of women employed in 1968 in a given industry) were positively associated with the rate of growth in all industries, except in mining and construction where female employment is still trivial.

About two-thirds of the increased employment share in the service-producing sector was concentrated in three divisions—in services, in finance, insurance, and real estate, and in retail trade. In 1968, these three divisions employed 67 percent of all women in the service-producing sector and each had female employment ratios ranging from 48 to nearly 58 percent. Also, these divisions recorded the three strongest annual rates of growth. Consequently, relative gains in female employment were substantial in each division; the three divisions combined accounted for 71 percent of the increased female employment in the service-producing sector. Thus, women made the largest numerical gains, as well as proportionate gains in industry divisions in which they already constituted a significant share of employment.

The increase in the proportions of female employment in the service-producing sector has had an important consequence on the overall earnings of women. Average weekly earnings in the service-producing sector are about two-thirds of those in the goods-producing sector primarily because of the comparatively low-paying divisions in the service sector—trade, finance, insurance and real estate, and services. Therefore, the faster growth of female employment in these divisions tends to depress the average weekly earnings of all women in nonagricultural jobs.

The data indicate that increases in the share of employment are closely associated with the levels of weekly earnings. For example, construction, with the second highest level of weekly earnings, experienced the highest increase in employment shares, while retail trade, with the lowest weekly earnings, scored the next to the lowest gain.

. . . And by industry division

Women have made significant gains in their share of employment in mining and construction industries, although female employment in each division is under 10 percent.[3] Increased employment shares accounted for 65 percent of the total female employment gains in mining and 74 percent in construction. Women made small numerical gains, but significant proportionate gains, in professional and technical occupations in mining.[4] Also, increased employment shares represented a large portion of total female employment gains in both durable and nondurable goods manufacturing, (where strong employment gains were made in professional, technical, and sales occupations). Women had strong gains in the Federal Government and in transportation and public utilities, where the gains were concentrated among professional, technical, managerial, sales, and operational occupations. They also made considerable strides into finance, insurance, and real estate, where more of them now are in management and sales positions. Retail trade, services, and State and local government recorded the lowest gains in employment shares (20 percent or

[1] Difference divided by actual change in employment of women.

NOTE: Due to rounding, data may differ from those shown elsewhere in this article.

less). Nearly all (97 percent) of the change in female employment in the Federal government was from increased employment shares, compared with 20 and 14 percent in State and local governments. However, employment growth of women was below average in the Federal government, but was slightly above average in the State and local government divisions.

From 1968 to 1978, women made significant strides in both durable and nondurable manufacturing, with increased employment shares representing 78 percent and 82 percent, respectively, of the total increase in female employment. Employment in durable goods grew at an annual rate of slightly under 0.5 percent, while female employment expanded 2.2 percent a year. Total employment in nondurable goods was essentially unchanged over the decade; thus, virtually all the growth was in female employment.

Women attained significant employment share gains in the manufacturing of furniture and fixtures and of instruments and related products, with the latter posting a particularly strong gain in total employment. The major durable goods employer of women, electric and electronic equipment, turned in an exceedingly sluggish performance over the 1968–78 period and, while women did increase their share, the increase was among the lowest of the durable manufactures. Non-electrical machinery had an above-average employment growth as well as an above-average female proportionate gains.

Five nondurables industries have posted employment declines since 1968. Three of them (textiles, apparel, and food products) were major employers of women, accounting for 61 percent of all the women employed in nondurables. However, women increased their share of employment in each of these industries, and in food products, the number of women actually increased. Printing and publishing displayed above-average employment performance; women increased their share at a rate nearly 4 times above that for all nondurable manufacturing. Women also achieved important gains in both the chemicals and the rubber and plastic products industries.

Women have more than doubled their employment over the decade in two transportation industries—local and interurban passenger transit and transportation services. Furthermore, they constituted a significant proportion of total employment in transportation services (45 percent in 1978). Increasingly, they have been accepted as bus drivers, especially in local transportation systems.

Employment in transportation service increased by 70 percent over the decade, with the share of women growing from 34 percent in 1968 to nearly 45 percent in 1978, as this industry responded to expanding travel needs. Women may be especially attracted to transportation service jobs because of the availability of employee discount fares and part-time employment opportunities.

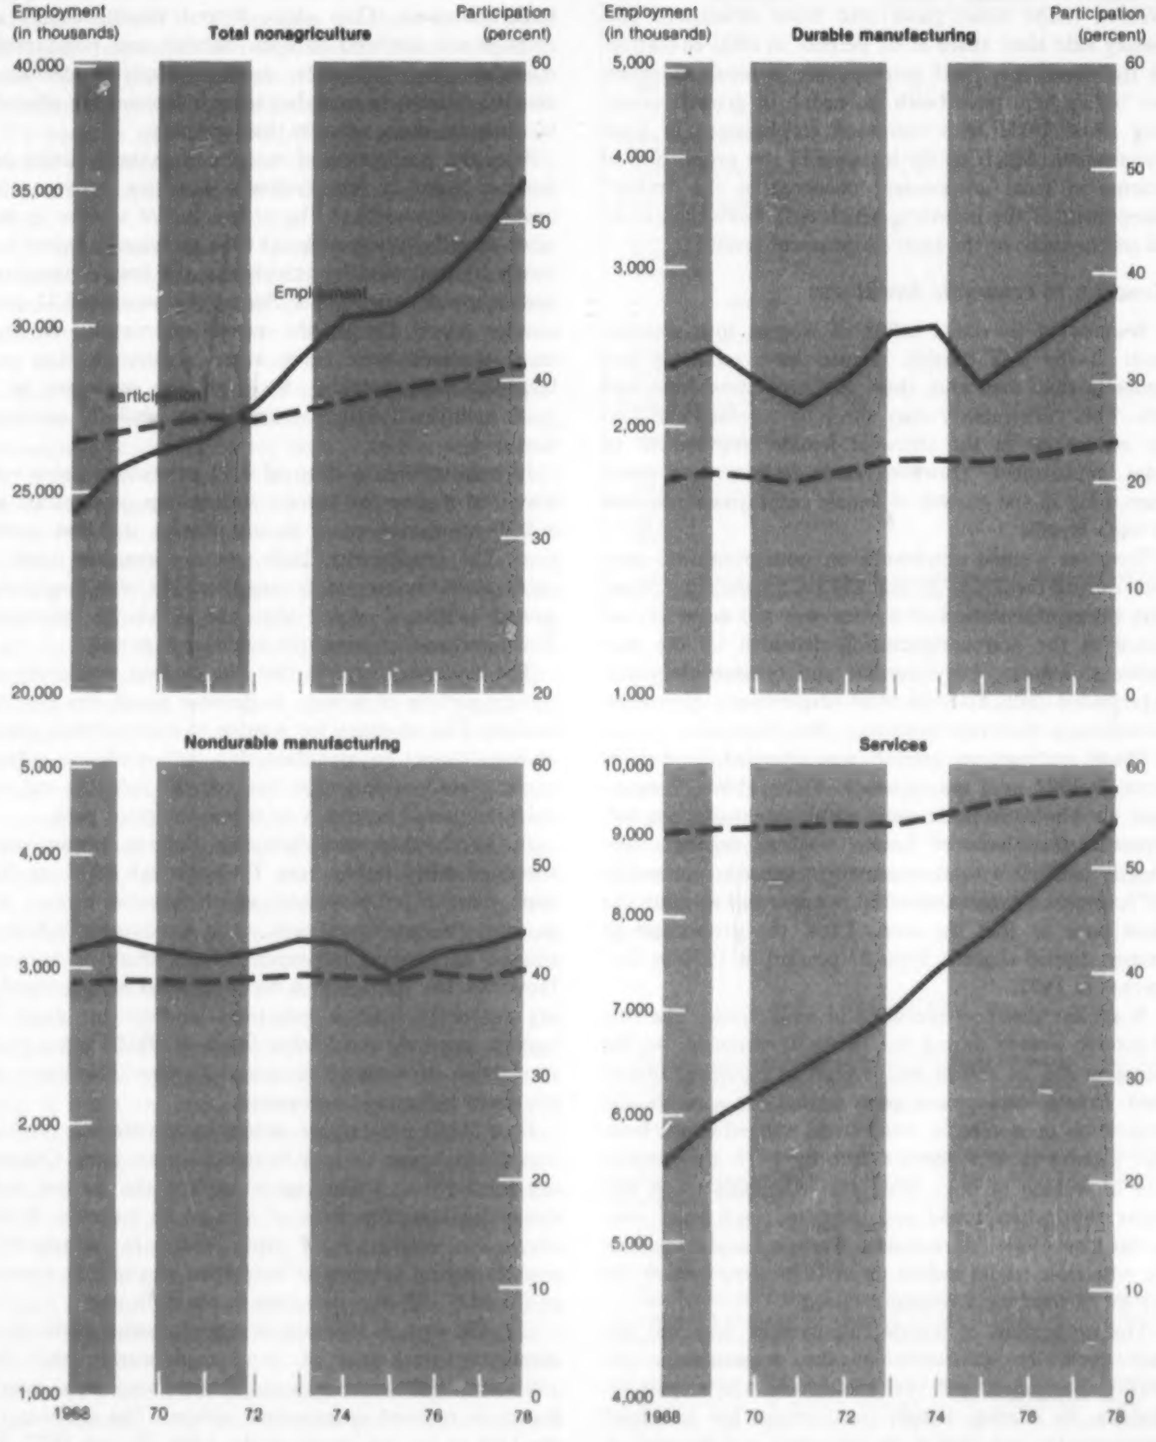
Employment of both men and women have expanded in the communication industry, yet the proportion of women dropped from 50 percent in 1968 to slightly under 46 percent in 1978. This decline reflects increased use of automatic telephone exchange equipment, which reduced the need for operators. Three retail sales industries, eating and drinking places, food stores, and furniture and home furnishings stores, experienced substantially above-average expansion in total employment. In food stores, female employment outpaced total employment, and the increase in their proportions was double that for all retail sales industries. Although total employment for automotive dealers and services posted a smaller than average gain, women made above-average proportionate gains in that component—their numbers grew at a rate nearly 3 times that of all retail sales employment.

About 34 percent of all women in retail trade are employed in eating and drinking places. This component grew at an annual rate of 6.3 percent, compared to the 3.5-percent rate for all retail trade. Women shared equally in this growth; thus, their employment share was little changed. The rapid growth of eating and drinking places undoubtedly reflects the proliferation of fast-food eating places related to increased family income and shifting life styles.

In the finance, insurance, and real estate division, women attained a greater than industrywide employment share into banking, credit agencies, insurance agencies, brokerages, and service industry. In each of these components, women represented more than 60 percent of total employment. Employment in real estate grew about the same as that in the industry as a whole; but women's share of total employment, at 36 percent, remained virtually unchanged over the 1968–78 period. Although total employment declined in the security, commodity brokerages, and services industry over the decade, female employment increased slightly.

Within the service division, women increased their share of employment above the industry's average in hotel, motel, and tourist places; business services; miscellaneous repair services; and in engineering and architectural services. Total employment gains were above average in business services and in engineering and architectural services. Nearly 42 percent of all women in the service sector are employed in the health services component. This component posted slightly better than a 6-percent annual rate of increase over the decade and, in 1978, 81 percent of its employees were women. The number of female employees rose dramatically, although the employment share was virtually unchanged. The proportion of women in legal services (71 percent) hardly changed between 1968 and 1978 although employ-

Chart 1. Number and proportion of women employed in nonagricultural industries, 1968-78 annual averages



ment in this component grew at an annual rate of 7.5 percent.

Employment in State education displayed a slightly stronger gain than that in total State government. Women made some gains into State education, but, merely held their share at 62 percent in local education. In the meantime, total employment in local education has barely kept pace (with an easing of growth occurring since 1975) with increased employment in local government. Much of the increase in the proportion of women in local government occurred in the "other" component of the industry, which rose more than overall employment at the local government level.

Reaction to economic downturns

Because of the large influx of women into employment in the past decade, women have relatively less seniority than men and, thus, less protection from layoffs. This vulnerability may show up as disproportionate reductions in the share of female employment to total employment. However, such declines may result from a lag in the growth of female employment, as well as from layoffs.

Data on women employees on nonagricultural payrolls during the 1969–70 and 1973–75 recessions reveal that the representation of women was not adversely affected in the nonmanufacturing divisions by the economic slowdown. Only durable and nondurable goods experienced reductions in total employment of women as well as in their representation. (See chart 1.)

Trade employment growth was retarded from 1970 through 1971 as a consequence of the 1969–70 recession. In wholesale trade, total employment did not fall; however, the share of female workers declined very slightly and when total employment growth resumed in 1972, female representation did not increase at quite the same pace as that for men. Thus, the proportion of women dipped slightly, from 23 percent in 1970 to 22.7 percent in 1972.

A similar situation prevailed in retail trade. The rate of growth slowed during the 1969–70 recession. As the recession ran its course and overall employment quickened, female employment gains trailed. As a result, the proportion of women in retail trade nudged down from 46.1 percent to 45.8 percent. But, by 1973, the proportion of women in both retail and wholesale trade was above the former peaks and increased each year, even during the 1973–75 recession. Female employment in the wholesale trades inched up in 1975, even though the industry's total employment declined.

The proportion of female employment does not appear cyclically vulnerable in the construction, the finance, insurance, and real estate, and the service industries. In mining, female employment has increased continuously and began to increase significantly in 1974 (although the number of women in mining is still negligible).

As previously mentioned, only in manufacturing was the share of women employees adversely affected during both recessions. Their share dipped simultaneously as employment declined in both durable and nondurable manufacturing. Generally, during periods of declining activity, women in manufacturing industries are affected by cutbacks more severely than are men.

Was the proportion of women in manufacturing industries more or less cyclically sensitive between the business contractions? The proportion of women in durable manufacturing dropped 0.56 percentage points between its peak and trough during the first contraction and dropped even further during the second, 0.72 percentage points. During the second contraction, employment declines were more severe, although they rebounded more quickly—the high was recovered in 2 years, compared with 3 years in the 1969–70 contraction.

In nondurables, a drop of 0.80 percentage point was sustained during the second contraction, in contrast to a 0.10-percentage point decline during the first recession. The prerecession high was not regained until 3 years after the second contraction, but was nearly regained within 2 years after the 1969–70 recession. Thus, in manufacturing, the evidence is mixed.

The evidence suggests that the cyclical sensitivity of the proportion of women in durable goods has not increased. The tendency for women to increase their share of employment in manufacturing will moderate subsequent overall employment drops in the industry and reduce the period necessary to regain the prior peak.

In nondurable manufacturing, female employment remained fairly stable from 1969 through 1977, as did their share of employment, which hovered around 40 percent. Except for tobacco, each nondurable industry showed an upward movement in the share of women. However, the impact of a compositional change resulting especially from a long-term employment drop in textiles, apparel, and leather (each of which has a high proportion of women) restrained an overall increase in the share of female employment.

Five of 10 nondurable industries manifested cyclical sensitivity during the two business contractions. Opposing employment trends again masked the general tendency for the proportion of women to increase. However, the sensitivity of their share in nondurable manufacturing appears to have been perceptibly greater in the 1973–75 recession than in the prior one.

Overall, women working in manufacturing incurred a disproportionate drop of employment during both the 1969 and 1973 contractions. These drops were manifested in reduced employment shares. The declines of the high to the low levels of the 1969–70 and 1973–75 recessions were 0.05 percentage point and 0.4 percentage point. The decline in manufacturing was more severe in the latter recession, as was the share of female workers.

During the 1973–75 recession, employment in durable goods responded in a significantly different manner from that in nondurable goods. Neither total employment nor the proportion of female workers peaked until 1974 (despite declining output). In contrast, in nondurable manufacturing, the employment and share of female workers peaks coincided with the cyclical peak of 1973.

The apparent tendency for disproportionate declines of female employment to be related to seriousness of employment cutbacks may be specious. This relationship prevailed during both contractions in the electric and electronic equipment industry, which employs the largest number of women of all durable goods industries. In contrast, fabricated metal products had large employment cutbacks during both recession periods, yet the proportion of female workers was not so acutely affected in the second contraction as in the first.

Nevertheless, caution should be used in ascribing too much significance to changes in female employment emanating from cylical changes. Changes at the aggregate level may reflect alteration in the proportion of women and the composition of the component industries. For example, a significant part of the large drop in the share of female workers in electric and electronic equipment during 1974–75 was due to an appreciable decline of employment (resulting from the introduction of integrated circuit technology) in electronic components and accessories, which accounts for about 21 percent of total employment in the industry. The nearly 4-percentage point drop in the share of women workers in the production of electronic components and accessories was not the result of a disproportionate decline of female employees, but rather of production workers, a group comprised almost entirely of women.

The extent of the impact of unequal reductions in the proportion of female employment can be shown, taking into account "disproportionate layoffs." In 1971, the year in which the share of female employment troughed in durable and nondurable manufacturing, 68,000 fewer women were out of work than if their share had equalled the overall share. (See table 3.) Their unemployment rate, adjusted for this, would have been about 6.7 percent, rather than the recorded 6.9 percent. In 1975, 98,000 fewer women would have been unemployed and the adjusted unemployment rate would have been 9.0 percent, rather than the 9.3-percent posted for that year. The obverse of a lessening in female unemployment would have been a corresponding increase in male unemployment with a consequent slight increase in the male unemployment rate.

Table 3. Employment of women in manufacturing industries during the 1969–71 and 1973–75 recessions

[Numbers in thousands]

Characteristic	Durable	Nondurable	All industries
1969–71			
Female share of employment:			
1969	20.5	38.9	...
1971	20.0	38.8	...
Female employment in 1971:			
Actual	2,128	3,101	...
Holding 1969 share constant	2,187	3,110	...
Female unemployment in 1971:			
Actual number	...	...	2,217
Adjusted number[1]	...	...	2,149
Actual rate	...	...	6.9
Adjusted rate	...	...	6.7
1973–75			
Female share of employment:			
1973	21.6	39.8	...
1975	21.2	39.0	...
Female employment:			
Actual number	2,276	2,981	...
Holding 1973 share constant	3,313	3,042	...
Female unemployment in 1975:			
Actual number	...	...	3,445
Adjusted number[1]	...	...	3,347
Actual rate	...	...	9.3
Adjusted rate	...	...	9.0

[1] Actual number of unemployed minus the amount attributable to "disproportionate layoffs" (the difference between actual and constant-share employment).

If one considers the effect of the proportions of female employment among the many components of a major industry group and the rates of employment growth among these various components, the total number of women affected may not even be as large as the above estimate. Thus, based on evidence from payroll employment data derived from a survey of establishments, the share of female employees is not significantly disproportionately affected when business activity declines. ☐

FOOTNOTES

[1] Detailed information on earnings of women by industry and occupation can be obtained from the Current Population Survey—a monthly survey of households conducted by the Bureau of the Census for the Bureau of Labor Statistics.

[2] Depending on base employment levels, equal changes in the proportion of female workers may produce differing indications regarding the changing importance of women in various industries.

[3] Data on occupations are from the Current Population Survey, a monthly survey of households conducted by the Bureau of the Census for the Bureau of Labor Statistics.

[4] The Associated General Contractors of America informed the Department of Labor that it would be unable to meet the 1979 Federal affirmative action goal for hiring women on construction jobs. The construction industry was required to fill 3.1 percent of its jobs with women by May 1979 and 6.5 percent by May 1981. An estimated 1.2-percent of the 4 million workers in the construction trade are women. See *The Washington Star*, Feb. 27, 1979, p. A-4, and *Monthly Labor Review*, May 1979, pp. 57–58.

Evaluating the 1975 projections of occupational employment

BLS' industry-occupation matrix projections proved better than those of alternative methods, even though staffing patterns were error prone; new Federal-State employment data should improve projection accuracy

MAX L. CAREY

Accurate occupational projections are highly prized by educational policymakers and by those planning careers: a clear vision of the future is the best tool for making such important decisions. But the pitfalls of attempting to chart unknown events are legendary. An early 20th century forecaster of occupational growth, for example, concluded that nearly all U.S. women would eventually be employed by the telephone company, based on its growth rate and the occupational structure of its work force. Few occupational projections have been as inaccurate. Even fewer have been completely correct. The vast majority lie somewhere in between, and their value must depend on some measure of the degree of error.

This article examines differences between BLS' projected 1975 occupational employment and actual employment.[1] It does not address the standard to be used in judging whether a projection is "good." The degree of error that produces a decision different from that made with a perfectly accurate projection might separate "good" from "poor" projections. But because of the uncertainty of other variables in the decisionmaking process, estimates of such a turning point would be conjecture. Nevertheless, decisionmakers can benefit by an assessment of the accuracy of the projected numbers, including an analysis of the projection method to identify sources of error.

In 1967, the Division of Occupational Outlook completed a matrix that described the relationship of employment in 162 occupations and 124 industries during 1960 and projected these relationships to 1975.[2] The primary data sources for occupational employment were the 1950 and 1960 censuses and, for industry employment, annual estimates from the BLS establishment surveys beginning from 1947. A revision of the 1975 matrix was completed in 1969, based mostly on additional industry data. Although the revision was not published, it was used as a resource for the occupational outlook program, and provides an opportunity for evaluating projections with more historical data. Due to a major change in the occupational employment classification system beginning with the 1970 census, only 76 of the 162 detailed occupations were sufficiently comparable for evaluation.

Evaluation of projection methodology disclosed weakness in the estimation of industry-occupation employment ratios. The adequacy of decennial census data as a basis for projecting changes in industry-occupation patterns has always been regarded with some suspicion by BLS analysts, and concern about these data was a major factor in the decision to launch a cooperative Federal-State program in 1970 for surveying occupational employment. The current analysis has found that the census-based ratio estimates were a far greater source of error in the occupational projections than the estimates of industry employment levels. In fact, a simulated matrix based on actual 1975 industry employment levels and the estimated ratios produced

---

Max L. Carey is a labor economist in the Division of Occupational Outlook, Office of Economic Growth and Employment Projections.

occupational totals that were no more accurate, on average, than the projections, suggesting that the ratios were so poor that they would have even negated the effect of perfect industry projections.

The unforeseen economic downturn of the mid-1970's reduced the accuracy of the occupational projections, although the damage was not as great as initially supposed. The projections presumed an unemployment rate of 3 percent in 1975. But the target year turned out to be the trough of the recession, and the actual unemployment rate was 8.5 percent. Consequently, employment in occupations that are sensitive to economic cycles, such as craft and operative occupations, generally was overprojected. Employment in these two groups had been growing, and almost reached projected levels by 1974, but turned down as economic conditions worsened in 1975. Underprojections did occur in 3 of the 9 major occupational groups despite the recession, and these errors might have been somewhat higher if economic conditions in 1975 had been as favorable as assumed.

The difference between projected and actual employment for the major occupational groups ranged from a 6.7-percent underestimate of clerical workers to a 9.1-percent overestimate of operatives. The average of the absolute percentage differences was 6.1 percent. The projections for detailed occupations had a much larger error, averaging 20.8 percent off 1975 employment levels. Differences between projected and actual employment tended to increase as the size of the occupation diminished. The availability of more reliable historical data for larger occupations could be expected to improve projection accuracy. The greater accuracy of projections for the occupational groups, however, also reflects the compensating effect of aggregation, because most group totals were obtained by summing projections for detailed occupations. In addition to being weak for small occupations, the projections were relatively inaccurate for occupations that declined in employment or grew very rapidly.

Several projection methods that would have been simpler and less costly than the matrix were explored. Among these, the most successful was linear extrapolation of employment trends in each occupation. These extrapolations averaged an absolute 26.2 percent off actual 1975 employment in the 76 detailed occupations compared to the 20.8 percent error for the matrix projections.

Projection methods and assumptions

The basic approach used to estimate future occupational employment requirements was to project total employment by industry, project occupational staffing patterns (ratios) by industry, and then multiply the industry totals by the ratios to obtain occupational estimates. The results were then summed across industries to obtain occupational totals.[3]

Projections of the occupational structure of each industry were based on examination of historical statistics and the analysis of the factors that influence occupational structure changes, such as new technology and changes in the product mix of industry. Employment requirements for many occupations, however, were projected independent of their relationships to industry employment. The projection of school teachers, for example, was based on an analysis of trends in pupil-teacher ratios and the projected school-age population. This technique was preferred in cases where such reliable predictive relationships could be established.

The 1975 projections were premised on certain assumptions about the size of the labor force, Armed Forces strength, the rate of unemployment, and other selected assumptions. Full employment was assumed in the target year, and defined as a civilian labor force with a 3-percent unemployment rate. This figure was selected based on the almost steady decline in the unemployment rate through the 1960's and the emphasis placed on federally assisted programs to further reduce unemployment. A total labor force of 92.6 million was projected for 1975, and it was assumed that 2.7 million persons would be in the Armed Forces, yielding a civilian labor force of 89.9 million.[4] With the assumed unemployment rate, the result was projections of 87.2 million employed and 2.7 million unemployed workers in 1975. The 87.2 million employment number was used as a control total for the occupational projections.

The economic recession of the mid-1970's negated the assumption of a full-employment economy in the target year. The unemployment rate in 1975 was almost triple the assumed 3-percent rate. Reflecting the impact of the recession, the projection of total civilian employment was 2.9 percent higher than the actual level of 84.8 million in 1975, as shown in the following tabulation:

	Employment (thousands)		
Labor force groups	*Projected*	*Actual*	*Percent difference*
Total	92,600	94,793	−2.3
Armed Forces	2,700	2,180	23.9
Civilian labor force	89,900	92,613	−2.9
Employment	87,200	84,783	2.9
Unemployment	2,700	7,830	−65.6

The overstatement of 1975 employment would have been even greater if the civilian labor force had been more accurately projected. Primarily because the number of women entering the labor force was greater than anticipated, the total labor force exceeded the projected level by about 2 million.[5] In addition Armed Forces strength was about 1 million lower than assumed. The net result was a civilian labor force of 92.6 million instead of the projected 89.9 million. If the total labor force had been projected correctly, the unemployment assumption would have resulted in a 5.9-percent overstatement of target year civilian employment, rather than the 2.9-percent error that actually occurred.

The economic downturn of the mid-1970's caused distortions in occupational employment that were of greater magnitude than the relatively small difference between projected and actual total employment. Because individual unemployment rates for each occupation were not specified in the assumptions, the effect of the recession on the accuracy of a projection for any given occupation is difficult to measure. Unemployment data for major occupational groups, however, indicate that the economic downturn generally had a greater effect on blue-collar occupations than other categories.

Base and target years

Ambiguity regarding the base and target years or the projection span complicated the evaluation. Although 1960 was the published starting point, some data for more recent years were available before the projections were completed. And, although targeted for 1975, the projections were intended to be indicators of long-term trends rather than precise estimates for 1975.

The matrix was developed with a 1960 base and a 1975 target year; it did not have estimates for any intervening year. The only comprehensive source of data on industry-occupation employment patterns available at the time the matrix was being developed was the 1960 census, and this continued to be the most comprehensive source until results from the 1970 census became available. Published estimates of total wage and salary employment by industry from the establishment survey and total employment by occupational group from the Current Population Survey (CPS), however, were available annually through 1965 at the time the matrix was being prepared. In addition, unpublished CPS estimates of employment in detailed occupations were available.[6] Clearly, the post-1960 industry employment trends were used in projecting industry employment levels. The trends for occupational groups also were considered at least as guidelines, even though the projections for most groups were the sums of detailed occupational projections rather than being independently developed. The use of unpublished CPS data on detailed occupations was not well documented in the description of projection methodology, but the CPS trends for many detailed occupations reportedly were disregarded because of their uncertain reliability.

The fact that some post-1960 data were used tends to bias measures of projection accuracy that relate to the entire 1960–75 span because greater accuracy might be expected as the projection period was shortened. To avoid this problem, an evaluation must focus on differences between projected and actual employment *levels*, rather than differences between actual and projected employment *changes*. The difference in levels is the same regardless of the base year.

The lack of a satisfactory basis for fairly judging the projected changes in occupational employment is unfortunate. Comparisons of levels alone generally have a conservative bias: projections for occupations which have relatively little employment change tend to get better marks than those which have the most change, as demonstrated in the following example. If employment in occupation A was projected to rise from 100,000 to 200,000 over a decade, but actually rose to 150,000, then 50 percent of the change was projected, and the error in level is −25 percent. If employment in occupation B was projected to rise from 100,000 to 120,000 in the same period, but actually reached only 105,000, then 25 percent of the change was projected, but the error in the level is only −12.5 percent. In terms of the proportion of actual change that was projected, A is better, but in terms of the difference between levels, B is better. Both kinds of accuracy are important. The accuracy of level is particularly important in estimating future occupational requirements, however, because projected levels are used in calculating replacement needs due to retirements and deaths.

Another problem concerns the target year. The projections were intended to be indicators of secular or long-range trends rather than estimates of employment at a future point, because it is understood that such estimates easily can be upset by unforeseen cyclical activity. Thus, it might have been wiser to describe the projections as levels that might occur in the mid-1970's or in the 1974–76 period. The projections would have been more accurate statements, with little inconvenience to users.

As previously indicated, the recession of the mid-1970's was at its worst in 1975, and the effect on occupational employment levels was not uniform. Ideally, an evaluation would judge the projections by occupational employment levels that would have existed had the recession not occurred, but this was not a practical approach. As an alternative, the 1975 projections for the major occupational groups also were compared with actual employment in both 1974 and 1976, when economic conditions were somewhat better.

Occupational groups

The direction of employment change between 1960 and 1975 was correctly anticipated for all of the nine major occupational groups, although employment in five was overprojected. Projection errors ranged from an approximate 1.2-million overstatement of employment in the operative group to a 600,000 understatement of clerical employment. The average absolute error for all groups was 535,000. Relative differences ranged from a 10.2-percent overprojection of farmworkers in 1975 to a 7.4-percent underestimate of nonfarm laborers. The average of the absolute percentage errors for all groups was 6.1 percent.

The difference between projected and actual 1960–75 employment change in each occupational group varied considerably. The anticipated increase in the number of professional workers was only 5 percent greater than the actual growth. In contrast, the projected gain in laborer employment was 85 percent lower than the actual increase. On average, about two-thirds of the employment change that occurred in each occupational group between 1960 and 1975 was projected.[7]

Estimates for white-collar groups generally were closer to the mark than those for blue-collar groups—reflecting the distortions in occupational patterns resulting from the 1973–75 recession. Because such distortions probably were greater in 1975, when the recession was at its worst, projections also were compared with actual employment in adjoining years. (See table 1.) Estimates of the error for the nine occupational groups averaged an absolute 4.8 percent off 1974 levels and 6.0 percent off 1976 levels, compared to the 6.1-percent average absolute error for the target year.

Professional, technical, and kindred workers. As projected, this major occupational group led in comparative rates of growth. Employment reached 12.7 million in 1975, an increase of 77 percent from the 1960 level, compared with an anticipated 73-percent increase. Thus, the projected number of professional and technical workers was only 2.2 percent lower than the actual number in 1975, the smallest error among the occupational groups. The actual number, however, probably would have been slightly higher if economic conditions in 1975 had been favorable, as assumed.

Managerial workers. Employment grew more slowly than anticipated in this group, increasing 21 percent between 1960 and 1975, compared with projected 28-percent growth. The number of managerial workers was expected to be 5.3 percent higher than the reported 8.9 million in 1975. The projected 9.4 million, however, was almost attained in 1976 when employment reached 9.3 million.

Salesworkers. Employment in this group was overestimated by 2.6 percent, a smaller than average error. The number of salesworkers increased from 4.2 million in 1960 to nearly 5.5 million in 1975, almost reaching the projected 5.6 million.

Clerical workers. The projected number of clerical workers, the largest of the occupational groups, was 4 percent lower than the actual number in 1975. Employment reached 15.1 million in 1975, a gain of 58 percent over the 1960 level, compared with a projected 52-percent increase. The difference between projected and actual employment for this group probably would have been greater had the recession not occurred.

Craftworkers. The number of skilled blue-collar workers was overestimated by 6.4 percent. Employment was almost 11 million in 1975, about 25 percent higher than the 1960 level, instead of the anticipated 33-percent gain. The error was significantly affected by the recession. A large proportion of craft workers are employed in construction and manufacturing industries, which are more sensitive to economic fluctuations than most other industries. Craft employment, however, had risen to about 11.5 million in 1974, almost reaching the 11.7-million projected level before decreasing as the economy worsened in 1975.

Operatives. Employment in the largest blue-collar group was overestimated by 9.1 percent, the second highest error among the occupational groups. Instead of rising from 11.4 million in 1960 to 14 million in 1975 as projected, employment peaked at 13.9 million in 1974, then dropped to 12.9 million in 1975—again reflecting the impact of the recession. Operative employment was concentrated in manufacturing industries, where unemployment rates averaged more than 11 percent in 1975.

Laborers. The 3.8-million employment projection for this group was 7.4 percent too low; and because laborers are employed primarily in manufacturing and construction, the underestimate would have been even larger if economic conditions had been more favorable. The number of laborers increased more rapidly than anticipated, peaking at 4.4 million in 1974, before dropping to about 4.1 million in 1975.

Service workers. The projection for this fast growing occupational group was too high. Employment was expected to increase from 8.3 million to 12.5 million between 1960 and 1975, a gain of 50 percent. The actual gain was 40 percent. Service industry employment, which finally reached the 1975 projected level in 1978, would have been projected more accurately but for the recession.

Farmworkers. The employment of farmworkers was overstated by 10.2 percent, the highest error among the occupational groups. Although a decline in farmworkers was projected, the extent of decline was underestimated. A 38-percent decrease in the 5.2-million 1960 employment level was projected, but a 44-percent decrease occurred. The recession probably was not a significant factor in the projection error for farmworkers.

Specific occupations

The evaluation of employment projections for detailed occupations was limited by data constraints. The

Table 1. Comparison of 1975 occupational group employment projections and actual employment in 1974, 1975, and 1976

[Thousands of workers]

Occupational group	Employment					Percent difference between projected and actual			Percent change 1960–75	
	Actual 1960	Projected 1975	Actual 1974	Actual 1975	Actual 1976	1974	1975	1976	Projected	Actual

Farmworkers	5,211	3,235	3,048	2,936	2,822	6.1	10.2	14.6	−37.9	−43.7

NOTE: Details may not add to totals because of rounding. Percent differences are based on unrounded numbers.

primary source of occupational employment data for the occupational matrix was the 1960 census, but the Census Bureau revised its system for classifying employment data by occupation for the 1970 census. Beginning in late 1971, the revised system was adopted for the Current Population Survey (CPS), the primary source of occupational employment data between decennial censuses. Primarily as a result of this classification change, projections for only 76 of the 162 occupations in the matrix were comparable with 1975 employment data estimated from the CPS. Comparability also was affected by survey differences. The CPS data have a larger sampling error than the 1960 census data that were used in developing the base year matrix. Sampling errors for small occupations represented sizeable proportions of the estimated actual employment. For example, the standard error for the smallest occupation with a CPS data source, asbestos and insulation workers, was about one-fifth of the 1975 estimated employment level of 29,500. The projection of 29,300 workers in this occupation could have been anywhere between about 23,400 and 35,200 without exceeding the sampling error (1 standard error of the estimate) for the estimate of actual employment. Although this example is extreme, it demonstrates the need for caution in comparing estimates of actual employment with projections. (For a more detailed explanation of this technical factor, see the appendix.)

Differences between projected and actual employment in the 76 detailed occupations ranged from −43 percent for personnel and labor relations workers to +136 percent for plasterers. (See table 2.) The absolute percentage errors for all 76 occupations averaged 20.8 percent. Two-thirds of the occupations, however, had errors lower than the average.

One way to judge projections is to compare them with the results obtained from simple alternative methods. The occupational projections were better descriptions of the future than extrapolations of trends in total employment for each occupation. Extensions of 1960–67 annual employment data by simple linear regression over time, which would have been an inexpensive and easy method of projecting, averaged an absolute 26.2 percent off 1975 actual levels compared with the 20.8-percent average absolute error for the projections. For about one-half of the occupations, however, the simple extrapolations of employment trends were more accurate than the projections.[8] Attempts to fit curves to the employment trends produced less accurate results than the linear extrapolations. Estimates also were developed with the projected civilian labor force used as the independent variable, but the results were relatively poor, being more accurate than the projections for less than two-fifths of the occupations.

Projection accuracy was related to the size of employment in an occupation. When weighted by employment in each occupation, the average absolute error drops from 20.8 percent to 14 percent, indicating that the largest occupations generally had the more accurate projections. Relatively accurate projections for the following four categories, each with more than 1 million workers in 1975, contributed substantially to the improved results: elementary school teachers; attendants, hospital and other institutions; waiters and waitresses; and stenographers, typists, and secretaries. The following tabulation shows how projection accuracy improved for occupations with more workers:

Number of workers in occupation	*Number of occupations*	*Average absolute percent error in projection*
Total	76	20.8
Less than 50,000	19	32.4
50,000 to 99,999	14	20.3
100,000 to 299,999	17	15.5
300,000 to 599,999	14	19.8
600,000 and more	12	11.2

Sampling errors for census estimates diminish relatively as employment size increases, so the historical data for large occupations would be expected to provide

Table 2. Comparison of projected and actual 1975 employment in selected detailed occupations

[Thousands of workers]

Occupation	Employment			Difference between projected and actual		Percent change	
	Actual 1960	Projected 1975	Actual 1975	Level	Percent	Projected	Actual

NOTE: Employment levels are expressed in rounded numbers, but percentage differences are based on unrounded numbers.

more reliable trends. The greater accuracy of projections for occupational groups, however, also reflects the compensating effect of aggregation, as most group totals were obtained by summing projections for detailed occupations. Within a group, overestimates for some detailed occupations tended to be offset by underestimates for others.

The direction of employment change between 1960 and 1975 was correctly anticipated for 64 of the 76 detailed occupations. Again, results were best in the larger fields of employment. The occupations for which the direction of change was identified had average employment of about 245,000 in 1960; those with projections in the wrong direction had an average of less than 107,000 employees. Moreover, only 4 of the 51 occupations with more than 50,000 workers in 1960 had projections that were in the wrong direction, while 8 of the 25 smaller fields had that mistake. Some of the differences, however, between projected increases and actual declines, or vice versa, were relatively small.

The poor performance in estimating future employment requirements for small occupations raises questions about whether BLS should be attempting to develop projections for occupations that lack reliable employment data because of sampling error or other problems. In an effort to provide users with estimates for a larger number of fields, possibly more harm than good is being done.

Employment grew in 60 of the detailed occupations between 1960 and 1975, and declined in the remaining 16. Increases were estimated more accurately than decreases. Projections for growing occupations averaged an absolute 17 percent off actual employment, while those for occupations with losses averaged 35 percent off. Projections of growth were closely divided between underestimates and overestimates of reported employment gains. Almost all employment declines were underestimated.

The direction of employment change was correctly anticipated for all but one of the growing occupations. The number of sailors and deckhands increased by about 1 percent instead of declining by 16 percent as projected. The standard error for the estimate of 1975 employment in this occupation was much greater than 1 percent, however, so a decrease actually may have occurred. In fact, a decrease seems likely because total employment in the water transportation industry decreased in the 1960's and early 1970's.

Occupations at either end of the employment growth spectrum generally had less accurate projections than those in the middle. As the following tabulation shows, occupations with the most rapid growth had the largest projection errors, and the slowest growth occupations had somewhat larger errors than those with moderate growth.

Percent growth in employment, 1960–75	*Number of occupations*	*Average absolute percent error in projection*
Average of all growth rates, 58.1 percent	60	17.0
Less than 20	12	20.5
20 to 39	16	13.1
40 to 59	11	16.6
60 to 89	12	14.2
90 or more	9	23.7

Target year employment usually was underestimated in the fastest growing occupations and overestimated in those with the slowest growth. Projections were lower than actual levels in 14 of the 15 fastest growing occupations, and higher than actual in 12 of the 15 with the slowest increases.

Decreases were not anticipated in 11 of the 16 occupations that declined in employment. Projections for four of these occupations were within the range of sampling error (1.6 standard errors of the estimate) for estimates of actual 1975 employment, but this limit was exceeded for plasterers, patternmakers, telephone operators, power station operators, machinists, and railroad engineers and brake and switch operators. The projections correctly identified postmaster, weaver, knitter, and locomotive engineer's helper as occupations which would decline in employment, although the rate of decrease was underestimated for three of these four.

Revised projections

A revision of the 1960–75 matrix improved the accuracy of the occupational projections somewhat. The revision was based on 2 years of additional information which had become available after the initial matrix was completed. The basic economic assumptions, such as the size of the labor force and the unemployment rate, remained the same, but projections of industry employment levels were revised in line with more recent data.[9] The industry-occupation ratios, however, continued to be based primarily on the 1950 and 1960 censuses. For about two-thirds of the industries, the revised employment projections were either as accurate or more accurate than the initial projections.[10] The effect of the revision on the accuracy of ratios could not be determined because industry-occupation employment patterns for 1975 have never been developed.

The average absolute 6.1-percent error for the nine occupational groups in the initial projection was reduced to 3.7 percent with the revision. The most significant improvement was a reduction in the overstatement of farmworkers from 10.2 percent to less than 1 percent. Errors in estimates for professional, managerial, and laborer groups also were reduced. The revised projections, however, were less accurate for the sales, craft, and operative groups.

The revision improved the accuracy of projections for half of the 76 detailed occupations included in the evaluation, and reduced the accuracy for the remaining half. The degree of error was lowered. The 76 occupational projections in the original matrix averaged an absolute 20.8 percent off actual 1975 employment levels; the revision reduced this to 19.4 percent, and several of the worst estimates were improved. The largest error, a 136-percent overestimate of the number of plasterers employed in 1975, was reduced to 53 percent. Large projection errors for civil engineers and for photoengravers and lithographers also were reduced substantially. Occupations with significantly less accurate projections as a result of the revision included weavers, machinists, airplane pilots and navigators, and airplane mechanics. Most of the changes reflected adjustments both in industry employment levels and staffing patterns. Changes in the airplane pilot and mechanic projections, however, were primarily a result of a revision in the air transportation industry projection, while the change in the plasterer estimate was almost entirely a result of an adjustment to the construction industry's occupational profile.

Considerable differences appeared when the original and revised projections were ranked according to accuracy. Only two occupations were among the 10 with the most accurate projection in each version. Even among each top 20, there were only 10 occupations in common. However, 14 occupations were common to the bottom 20 for each version. Because errors for the best projections fell within a much more narrow range than those for the worst projections, the order at the top of the scale was more sensitive to the revision.

Although several major changes were made and rankings were upset, the new estimates for most occupations were fairly close to the original projections. The revised figures averaged an absolute 11.4-percent change from the initial estimates, and the differences for almost three-fourths of the detailed occupations were smaller than the average. In addition, similar patterns were observed in both sets of projections. The largest occupations usually had the most accurate projections, and employment increases were estimated much more accurately than declines. In both the original and revised estimates, errors for occupations that declined in employment averaged about twice as high as those for occupations with employment growth. Both declines and rapid increases in employment generally were underestimated.

The relatively small difference between the initial and revised projections suggest that it may not be worthwhile to revise matrices unless additional years of data on both industry employment and industry-occupation ratios are available.

Matrix errors

A major objective of this evaluation was to isolate the effects of errors in the matrix elements that determine occupational employment in the target year—projected employment by industry, and projected occupational staffing patterns for each industry (industry-occupation ratios). Ideally, the error caused by each of these factors would be determined by developing simulated matrices that combine actual data for one factor with projected data for another. Unfortunately, because actual ratios for 1975 were not available, the effect of projected industry employment totals could not be isolated, and therefore an analysis of both factors and their interaction was not possible. However, a simulated matrix based on actual industry employment totals and projected ratios was developed, and the resultant set of occupational projections was compared to actual occupational totals to determine the effect of the projected ratios alone.

The revised matrix was used for the simulation because the computer system that processed the initial version was incompatible with later systems. Resources did not permit development of 1975 industry totals for this exercise. As an alternative, data for the simulation were obtained from a set of 1974 industry employment totals which had previously been developed as a base for the 1985 matrix projections. However, the use of actual data from 1974, rather than from 1975, should give a more valid measure of ratio errors because recession-induced distortions in industry occupational relationships were probably less pronounced in 1974.

Contrary to what might be expected, the simulated projections turned out to be less accurate than the projections. Revised 1975 projections for the detailed occupations averaged an absolute 16.2 percent off actual 1974 employment levels. When actual industry employment levels were substituted for projected levels in the matrix, and the ratios remained as projected, the average absolute error for the occupational projections increased slightly to 16.3 percent. This comparison indicates that the ratios, rather than industry levels, were the primary source of error in the projected occupational totals. That is, because perfect industry employment projections would not have improved the accuracy of the occupational projections, the fault must have been mostly with the ratios.

The problem with projected ratios was more pervasive than the small difference in the two average errors might suggest. The simulations were worse than the projections for 49 of the 76 occupations in the study, but resulted in substantial improvements for many of the remaining 27, thus bringing the average error for the simulations more in line with that of the projections. (See table 3.) Among the estimates benefiting

Table 3. Comparison of projections and simulations of 1975 employment and 1974 actual employment in selected detailed occupations

[Thousands of workers]

Plasterers	39.5	38.7	26.6	12.9	48.5	12.1	45.5

[1] The accuracy of the occupational projection was reduced as a result of reinforcing errors in the projections of industry-occupation ratios and industry employment levels.

NOTE: Projections of 1975 employment used here are based on the 1969 revision. Employment levels are expressed in rounded numbers, but percentage differences are based on unrounded numbers.

most from the actual industry employment data were those for airplane pilots and navigators, aerospace engineers, and postal clerks, reflecting the fact that the industries where these fields are concentrated—air transportation, aircraft manufacturing, and post office—had some of the least accurate projections of industry employment levels.

When weighted by employment, the average absolute error for the simulated projections dropped from 16.3 percent to 12.6 percent, an indication that the ratio estimates were better for the larger fields of employment. The error for occupations with fewer than 50,000 employees in 1974 was almost twice that of those with a half million or more workers. Weak ratio estimates for small fields of employment may be related to problems with historical data on industry-occupation patterns. Survey errors were relatively large for census estimates of total employment in small occupations, and the problem may be compounded when these totals are disaggregated among the industries. A large number of occupations are so widely dispersed that only a fraction of 1 percent is found in many industries.

The failure to anticipate the impact of technological change and other factors that affect occupational needs also contributed to ratio errors. In estimating ratios for knitters, for example, it was assumed that increases in the demand for knit goods would more than offset the employment effect of laborsaving technology. Although total employment in the knitting industry grew even more than projected, employment in this occupation declined as a result of larger capacity, higher speed machinery and other technological developments. Misassessments of the effect of technological developments also contributed to overprojected demand for plasterers, weavers, telephone operators, and several railroad occupations. In most cases, the laborsaving technology had been identified, but its future impact was difficult to project because data were either insufficient or nonexistent.

Compensating errors in the estimates of industry employment levels and ratios improved the accuracy of projections for 49 of the 76 occupations.[11] For example, total employment in the health services industry (excluding hospitals), where almost all optometrists were expected to be employed, was underprojected by about 12 percent, yet employment in this occupation was overprojected by about 4 percent. From this evidence, it can be concluded that an overstated ratio for optometrists almost offset the effect of an industry projection that was too low. The most accurate projections generally were products of this kind of counterbalancing. Compensating errors however, were not entirely the result of chance. In some cases, occupational projections that were developed independently conflicted with industry employment projections and, in adjusting these projections for consistency, ratios sometimes were distorted.

Errors caused by the two factors were reinforced for about one-third of the occupations, many of which had the least accurate projections. Occupations with reinforcing errors are identified by footnote in table 3; those not noted have compensating errors, with the exception of postmasters, which had no error at all because the ratio projection for this occupation was perfect.

New projections

Although the occupational projections were off the mark for many reasons, including the economic downturn in 1975, the evaluation has established that the ratio estimates were the largest source of error. These estimates were based on scanty data for trends in the occupational structure of industries. Although the projections were made in the late 1960's, the only comprehensive sources of historical data on ratios were the 1950 and 1960 decennial censuses. A long recognized need for current, detailed data on industry staffing patterns prompted the initiation of the cooperative Federal-State program, Occupational Employment Statistics (OES), in 1970. Data on employment by industry is now collected in 3-year cycles for more than 2,000 occupations through the OES survey. Through March 1979, 46 States and the District of Columbia were cooperating in the program, and BLS plans to complete the development of an OES-based 1980–90 national matrix in 1981.[12]

The recession in 1975 adversely affected the projections for many of the blue-collar occupations concentrated in construction and manufacturing industries. Alternative projections could address the problem of cyclical fluctuations. Rather than preparing projections based on one set of assumptions about the economy in the target year, alternative projections could be developed with different assumptions about the unemployment rate, the GNP, and other variables. BLS took a step in that direction in 1976 by developing 1985 industry-occupation matrices based on different sets of assumptions or scenarios about the economic policies that the Federal government might follow to sustain a recovery from the 1973–75 recession.[13] To assess the extent that occupational employment might be affected, industry employment projections based on each scenario were translated into occupational projections by applying them to fixed matrix ratios. Occupational projections based on two versions of what the economy might look like in 1990 are in preparation. As a refinement to the method used for 1985 estimates, matrix ratio patterns will be projected for each version of the 1990 economy rather than using the same pattern for both. One of the limitations of the scenario approach, however, is that the effect of each assumption cannot be isolated. Nevertheless, sensitivity analysis can isolate the effects of specific alternative assumptions.

Continuing analysis of the accuracy of projections is an important activity in improving their reliability. Evaluation of previous employment projections will become a regular part of the occupational outlook program. Actual employment data soon will be available for comparison with the 1980 occupational projections. □

APPENDIX: Technical factors

Resource constraints precluded construction of a 1975 matrix for the purpose of evaluating the occupational employment projections. Consequently, 1975 employment levels had to be estimated from (1) base year matrices for 1974 and 1976, which had already been developed by the Bureau in preparing and revising 1985 projections, and (2) from Current Population Survey (CPS) data, the primary source of occupational data for matrices between decennial censuses. The evaluation also was handicapped by a loss in the continuity of comparable employment data as a consequence of a revision in the occupational classification system used by the Census Bureau. In addition, relatively large sampling errors for CPS estimates of actual 1975 employment were a problem for some occupations.

Much of the occupational data from the 1960 Census, which was the principal data base for the projected 1975 matrix, is not comparable with CPS data collected after 1971. The 1960 Census system for classifying employment by occupation and industry was revised for

FOOTNOTES

[1] Evaluations of earlier occupational projections are described in Sol Swerdloff, "How good were manpower projections for the 1960's," *Monthly Labor Review*, November 1969, pp. 17–22.

[2] The Bureau's occupational projections for 1975 were first published in *Occupational Employment Patterns for 1960 and 1975*, Bulletin 1599, Bureau of Labor Statistics, December 1968. The projections also were presented in a corollary report, *Tomorrow's Manpower Needs*, Volume IV, Bulletin 1606, Bureau of Labor Statistics, February 1969. The projections evaluated in this article were obtained from the latter publication. There are minor differences in estimates presented in the two publications.

[3] For a detailed discussion of the methodology used in developing industry employment projections, see *Tomorrow's Manpower Needs*. pp. 5–8. The industry employment projections represented the collaborative efforts of several research staffs in the Bureau, including those working on technological change and productivity, economic growth, and occupational outlook. The general structure of employment by industry, however, was developed through an economic growth model which used an input-output approach.

[4] See Sophia (Cooper) Travis and Denis F. Johnston, "Labor force projections for 1970–80," *Monthly Labor Review*, February 1965, pp. 129–40.

[5] Evaluations of labor force projections for 1975 are described in Paul M. Ryscavage, "BLS labor force projections: a review of methods and results," *Monthly Labor Review*, April 1979, pp. 15–22.

[6] In more recent times, the CPS data and industry employment estimates were used to construct base matrices for years between decennial censuses. For example, the Bureau developed a 1974 base year matrix for its 1985 occupational projections, then a 1976 base for a revision of these projections. The detailed occupational totals in these matrices are a refinement of the CPS estimates.

[7] If 1965 is regarded as the starting point for the projections, the performance is not as good. The percentage of employment projected for the occupational groups averages about 52 percent if the change is measured from 1965 to 1975, compared to about 68 percent if change is measured from 1960 to 1975. The better performance when the span is greater is in part due to the projections being credited for some of the employment changes that already had occurred. As pointed out in the explanation of the problem with identifying the base year, data on occupational group employment were already available through 1965 at the time the projections were being prepared, and measures of accuracy that center on the amount of change projected will reflect this bias. The recession also was a factor, however, in that some of the employment gains that took place after 1965 were erased by the economic downturn in the mid-1970's. Employment in the operative group in fact was lower in 1975 than in 1965, although it had grown through the late 1960's and early 1970's. If this occupation is excluded from the average, the difference for the two time spans is reduced substantially. Excluding operatives, the projections accounted for an average of about 73 percent of the employment change in occupational groups during the 1960–75 period, and an average of about 71 percent of the change during the 1965–75 period.

[8] Extrapolations were based on 1960 Census data and 1962–67 CPS data (1961 data were not available). Comparable CPS employment series were not available for 4 of the 76 occupations in the study. Thus, extrapolations were developed for only 72 occupations. Extrapolation for 2 occupations resulted in negative employment in 1975; these negative numbers were arbitrarily adjusted to positive employment levels of 100 workers. Although the matrix projections used data only through 1965, data were available through 1967 by the time the matrix was submitted for publication. Because of the amount of time required to prepared the matrix, it was difficult to incorporate changes that reflected the latest data. Simple extrapolations, on the other hand, can be prepared in a very short time, making it easier to take advantage of the latest data.

[9] BLS later developed three alternative sets of industry employment projections for 1975 as a part of a contract with the U.S. Arms Control and Disarmament Agency to study the economic impact of a withdrawal from Vietnam. For a description of these projections, see *Projections of the Post-Vietnam Economy*, Bulletin 1733, Bureau of Labor Statistics, 1972. For an evaluation of the basic alternative set of industry employment projections, see Paul T. Christy and Karen J. Horowitz, "An Evaluation of BLS Projections of 1975 Production and Employment," *Monthly Labor Review*, August 1979, pp. 8–10.

[10] The measure of improvement in the accuracy of industry employment projections was based on estimates of total employment obtained from a 1974 base year matrix because a 1975 base year matrix was not available.

[11] The presence of compensating errors for an occupation was difficult to determine with certainty because the lack of data on actual ratios for the target year prevented isolating the effect of errors in industry projections alone. As a rule, however, errors in the industry and ratio projections are compensating for an occupation if (1) the sign of the projection error (table 5, fourth column) is different than the sign of the result of subtracting the simulation error (table 5, seventh column) from the projection error, or (2) the signs of the projection and simulation errors in these two columns are the same, but the projection error has a lower absolute level.

[12] For a description of the OES program, see *Occupational Employment Statistics Handbook*, Bureau of Labor Statistics, April 1979.

[13] See Max L. Carey, "Revised occupational projections to 1985," *Monthly Labor Review*, November 1976, pp. 10–21.

the 1970 Census, and beginning in late 1971, the revised system was adopted for the CPS. Interrelationships between the two systems were quantified in the Census publication, *Technical Paper 26, 1970 Occupation and Industry Classification Systems in Terms of Their 1960 Occupation and Industry Elements.* According to the information in this report, all nine occupational groups had 96 percent or better comparability between the two classification systems. Specifically, if the 1960 labor force data were retabulated, 95 percent or more of the labor force reported in a particular occupational group under the 1960 classification system would remain in the same group under the 1970 system, and these workers would represent 95 percent or more of the total for that group. At a more detailed occupational level, the comparability gap was wider. Of the 297 occupations in the 1960 classification system, 171 had 90 percent or better comparability in the 1970 system. About one-half of these occupations, however, were not included in the matrix. In addition, the accuracy of some of the projections that were based on historical data from sources other than the census could not be verified. After eliminating occupations which were less than 90 percent comparable and those which had verification problems, the evaluation of projections was limited to 76 of the 162 detailed occupations covered in the matrix.

Estimates from the CPS were subject to greater sampling variability than those from the decennial census. For an occupational estimate of 50,000, for example, the standard error would be about 900 if the data were from the 1960 Census, and about 6,700 if the data were from the CPS. Projections for several occupations were within the range of sampling error for CPS estimates of actual employment in 1975. Projections for the following occupations were within one standard error of the estimate:

Compositors and typesetters
Asbestos and insulation workers
Crane, derrick, and hoist operators
Pharmacists
Dietitians and nutritionists
Airplane pilots and navigators
Cabinetmakers
Cement and concrete finishers
Furnace tenders, smelters, and pourers
Metal molders
Millwrights
Jewelers and watchmakers
Railroad conductors
Sailors and deckhands

If the measure is set at 1.6 standard errors of the estimate, projections for the following additional occupations are within the range of CPS sampling error:

Waiters and waitresses
Bartenders
Clergy
Meat cutters and butchers, except meat packing
Roofers and slaters
Heat treaters and annealers
Log and lumber inspectors
Locomotive engineers' helpers

Comparability of occupational employment estimates also is affected by other differences between the census and the CPS. Among these are the more extensive training and experience of the CPS enumerators than the census enumerators, differences in format of schedules, and differences in methods used to process the original data. In addition, occupational estimates from the CPS were annual averages of 12 monthly estimates, whereas the Census data were collected only for April.

Dental and vision care benefits in health insurance plans

As medical care costs increase, dental and vision care insurance become more important; most of the plans studied were financed by employers, and there were restrictions and limitations on use of services, especially for dental care

DONALD R. BELL

Dental care and vision care have been among the fastest-growing areas of employee health insurance in recent years. Between 1974 and 1977, the latest date for which data are available, the proportion of employees covered by dental care insurance doubled or tripled, depending on the measure used; the proportion covered by vision care insurance increased by about one-half.[1]

Both employees and employers are interested in extending insurance coverage to areas that are important in terms of consumer cost. According to the Bureau of Labor Statistics' Consumer Price Index, dental care costs increased at annual rates of 8.8 percent between 1974 and 1977, and 7.7 percent between 1977 and 1979. Vision care costs increased 7.1 and 5.3 percent per year during the same periods. These increases were less than the increase in the cost of medical care, which rose at a rate of 9.8 percent a year from 1974 to 1979. However, for most employees, the bulk of the cost of medical care (physicians, hospitals, and prescription drugs) was covered by insurance, but for many, dental and vision care was uninsured.

Dental and vision care plans vary considerably in terms of services covered, types of payment made, coinsurance provisions, deductibles, maximum benefits, and other characteristics. This article outlines the principal features of dental and vision care plans included in the Bureau of Labor Statistics' *Digest of Selected Health and Insurance Plans*, 1977–79.[2] The 148 health insurance plans in the *Digest* are not necessarily model plans, nor are they a representative sample of all health insurance plans. However, they cover large numbers of workers in major industries, set or reflect trends, or are examples of different approaches to health insurance planning and, therefore, illustrate the characteristics and features of a variety of health insurance plans in private industry.

Typically, dental and vision care benefits are found in plans that also have protection against catastrophic illness, usually through major medical benefits. Health plans are considered as including dental and vision care if the benefits are separately provided as part of basic health benefits or if they are provided by major medical benefits, unless coverage was limited to dental surgery or accident care.

Nearly three-fifths (88) of the 148 health plans in the *Digest* provided out-of-hospital dental care; two-fifths (56) of the plans included benefits for out-of-hospital vision care. However, 3 dental and 10 vision care plans were part of multiple choice health insurance programs and are not discussed in this article.[3] Hence, this analysis includes 85 out-of-hospital dental care plans in effect as of July 1979, and 46 such vision care plans.

Dental coverage

All of the 85 plans provided diagnostic, preventive, restorative, and prosthodontic services, and 56 of them

---

Donald R. Bell is an economist in the Office of Wages and Industrial Relations, Bureau of Labor Statistics. Cynthia Thompson, of that office, assisted in the preparation of this article.

also covered orthodontic services, which are frequently more costly than other dental services.

Diagnostic and preventive services include examinations of the mouth, X-rays, cleaning, fluoride treatments, space maintainers, and consultations. Restorative services and treatments cover routine fillings (such as amalgam, silicate, acrylic, or synthetic porcelain), as well as inlays, onlays, gold fillings, and crowns. In addition, out-of-hospital oral surgery such as root resections and removal of impacted teeth, root canal therapy, and treatment of gums are included in this type of benefit.

Prosthodontic services typically include initial installation, repair, and replacement of removable and permanent dentures and bridgework. Orthodontic services cover treatment to correct or prevent irregularities in the position of the teeth and include X-rays, surgery, and the application of braces or similar devices.

The proportion of health plans with dental coverage varied among employee groups, ranging from 51 percent of the plans for nonoffice employees to 64 percent for the office and for the nonoffice and office (all employees) plans.[4] All dental plans provided coverage for preventive, restorative, and prosthodontic care, but a greater percentage of dental plans covering only office employees provided orthodontic services. (See table 1.)

Employers paid the full cost of dental insurance for employees and their dependents in 74 (or 84 percent) of the 85 plans. Eighty-seven percent of the plans that covered retirees age 65 or over were fully financed by the employer, as were 78 percent of those that provided coverage to retirees under age 65. The following tabulation shows the number of plans that are financed by employers or by employers and employees:

	Employer	*Employer and employee*
Active employees . . .	74	11
Retired employees:		
Under age 65 . .	35	10
Age 65 or over .	26	4

Table 1. Dental services provided in health insurance plans by employee group and reimbursement arrangement, July 1979

Employee group or reimbursement arrangement	Diagnostic and preventive services	Restorative services and treatments	Prosthodontic services	Orthodontic services
All plans	85	85	85	56
Employee group:				
Nonoffice only	36	36	36	23
Office only	21	21	21	15
Nonoffice and office[1] . .	28	28	28	18
Reimbursement arrangement:

60-70 percent . .	0	0	4	2
50-60 percent . .	0	4	36	39
Scheduled cash allowance	17	19	[2]20	8

[1] Employees covered by dental plans having the same benefits for nonoffice and office employees.

[2] Includes one plan (Doll Manufacturers plan, New York, N.Y.) providing full service benefits at the union's dental center for diagnostic and restorative services, but paying for dentures by scheduled allowances.

[3] Includes plan that pays 100 percent of charges for preventive services and 95 percent for diagnostic services.

With few exceptions, dental care benefits for retirees were the same as those for active employees. Retirees under age 65 had their dental benefits continued under 45 of the 85 plans with dental coverage. Older retirees were less likely to have dental benefits continued—only 30 of the plans had benefits for retirees age 65 or older.

Reimbursement provisions of dental plans

Restrictions on dental care were nearly equal among plans regardless of employee groups covered, although maximums for orthodontia and deductibles for specified services were more frequently found in plans covering only office employees. Like most other types of health insurance, dental plans have reimbursement arrangements to prevent abuse by the insured and, thus, keep down the insurer's costs.

There are three basic reimbursement arrangements: a nonscheduled cash allowance, which pays a proportion of the reasonable and customary charge for a procedure; a scheduled cash allowance, which pays up to a specified amount for a procedure; and a full service payment, which pays the full reasonable and customary charge for a procedure.

The most common reimbursement arrangement in the dental plans studied was the nonscheduled cash allowance. This procedure applied to all services except orthodontic in 65 of the 85 plans; 17 plans used a scheduled cash allowance, and 3 provided full payment. Nonscheduled cash allowances were common for orthodontic services—they were used by 48 (or 86 percent) of the 56 plans providing orthodontia. Orthodontic services were covered in three-fourths of the plans which paid nonscheduled cash allowances for other services, compared with fewer than one-half of those which paid scheduled cash allowances.

Plans with nonscheduled cash allowances were analyzed according to the proportion they paid of the reasonable and customary charges for each of the major dental services. Diagnostic and preventive care was the only service for which the majority of the plans paid the full reasonable and customary charge. Slightly more than one-half of the plans paid 80 or 85 percent of the full charge for restorative services and treatments; about three-fifths paid approximately 50 percent of the charge for prosthodontic services; and nearly four-fifths paid only 50 percent of the reasonable and customary charge for orthodontia. (See table 1.)

best copy available

The proportion of the charge paid for dental services appeared to be related to the cost of the procedure. For example, diagnostic and preventive care services, which include low-cost dental procedures, were fully paid by 34 of the 65 plans with nonscheduled cash allowances. The more expensive restorative services were typically paid at 80 to 85 percent of reasonable and customary charges, prosthodontic and orthodontic services, which are even more costly, were paid at 50 to 60 percent.

Two-thirds of the plans with scheduled cash allowances allowed $100 to $200 for the most expensive restorative service procedure and nearly three-fourths allowed from $100 to $300 for the most expensive prosthodontic procedure. Allowances were higher for a complete course of orthodontic treatment. For example, Dow Chemical Co. employees are allowed $50 for preliminary X-rays and diagnostic costs, $225 for the first month of active treatment, and $30 for each succeeding month. The time required for such treatment is usually 1 or 2 years. Thus, the amount payable under the Dow plan for a 2-year course of orthodontic treatment could be as much as $965, compared with the $205 allowance for the most expensive prosthodontic procedure.

There were exceptions to the typical 80 to 85 percent payment for restorative services. About 1 of 3 plans providing this service paid 100 percent for certain procedures, such as root resections and oral surgery. About 1 of 2 provided only 50 to 60 percent reimbursement for crowns, inlays, and gold fillings.

The lower percentage payment provided for crowns may be explained by the usually higher dollar cost of such procedures. The higher percentage payment for oral surgery and related benefits may be related to the fact that these services either are or had been covered by basic surgical benefits. For example, in the Uniroyal and Goodyear plans negotiated with the United Rubber Workers, procedures such as oral surgery, root resections, and gingivectomy, which were formerly covered under surgical benefits at 100 percent, are covered under dental benefits at that rate either in or out of hospital. Plans negotiated by the Steelworkers, such as the one with the American Can Co., provide 100 percent coverage under both surgical and dental benefits. However, in-hospital services are paid under surgical benefits and out-of-hospital services are paid under dental benefits.

A few of the plans encouraged the employee or dependent to visit a dentist annually by gradually eliminating, for those who did so, the copayment requirement for diagnostic and restorative services, or for diagnostic, restorative, and prosthodontic services as a group, over a 3-year period. In the metalworking industry plan negotiated by the Machinists' union and in the Prudential Insurance Company's plan for insurance workers, benefits in the first year are provided at 70 percent and increase by 10 percentage points each year, if the insured receives annual dental checkups, until it reach 100 percent in the fourth year. Such plans are apparently designed to encourage preventive care and thereby lower overall costs in the long run (although short-term costs may be higher), while providing higher levels of coverage.[5]

Another method of cost control is to limit the frequency with which a service is provided. Many plans, such as the Central States Trucking Industry-Teamsters plan, restrict routine oral examinations, cleaning, and bite-wing X-rays to once during a 6-month period; however, a few plans, such as the American Telephone and Telegraph Co.-Communications Workers plan, while covering such expenses twice during a 12-month period, do not specify when such expenses must be incurred. In 35 percent of the plans, more complete examinations, including full mouth X-rays were limited to once in 36 months. The replacement of dentures frequently requires proof that the existing bridgework cannot be made serviceable or that 3, 4, or 5 years have elapsed since the installation of the original dentures. The latter limitation is found in 49 percent of plans offering prosthodontic benefits.

Setting a maximum benefit amount to be paid during a specified period is another way to control costs. (See table 2.) Yearly maximum amounts for diagnostic, restorative, and prosthodontic services as a group, were specified in 58 of the 85 plans, and lifetime maximum amounts were specified in 7 other plans (including plans

Table 2. Maximum benefits and deductibles of dental care plans, July 1979

Reimbursement restriction	Total plans	Employee group: Nonoffice only	Employee group: Office only	Employee group: Nonoffice and office [1]
All plans	85	36	21	28
Plans that provided maximums for:				
All dental services, including orthodontia				
Yearly	5	0	2	3
Lifetime	3	1	1	1
Diagnostic, restorative, and posthodontic services [2]	58	24	14	20
Yearly	7	3	3	1
Lifetime

Yearly	49	21	14	14
Lifetime				
Plans that provided deductibles for: [3]	4	3	1	0
All services	28	9	12	7
Specified services				

[1] Employees covered by dental plans having the same benefits for nonoffice and office employees.

[2] Some plans have separate maximum benefit amounts for certain services or courses of treatment.

[3] Some plans have separate deductible amounts for certain services, and 6 plans have combined dental and major medical deductibles.

providing dental benefits as part of major medical benefits). Yearly maximums ranged from $500 to $2,000 for dental services other than orthodontia; however, nearly half of the maximums were $750. Lifetime maximums (except in plans with dental benefits included under major medical) for services other than orthodontia ranged from $5,000 to $25,000, with most plans specifying $5,000. In contrast, of the 56 plans with orthodontia, 49 had a lifetime maximum for such services. Maximums ranged from $408 to $3,000, but most plans allowed between $500 and $750 for lifetime benefits. A few plans had overall maximums which applied to all benefits, and some plans had both yearly and lifetime maximums applicable to benefits other than orthodontia. For example, the Dow Chemical-Steelworkers' plan had a yearly maximum of $750 and a lifetime maximum of $5,000 for such services.

Another control mechanism is the requirement that the insured pay the first part of any expense incurred—the "deductible." Thirty-two of the 85 plans required the employee to pay an annual or lifetime deductible. A deductible for a group of dental services was specified in 28 of the plans; 11 required the deductible only for diagnostic and preventive, and prosthodontic services as a group; the remaining 17 required a deductible for all services, except diagnostic and preventive services. Dental plans may not require a deductible for diagnostic and preventive services because of the relatively low cost of these services and because such care may help avoid future high-cost procedures.

Table 3. Reimbursement arrangement of vision care plans, July 1979

Reimbursement arrangement	Total plans	Employee group		
		Nonoffice only	Office only	Nonoffice and office[1]
All plans	46	27	6	13
Plans that provided:				
Full service				
Eye examination	4	3	0	1
Eye glasses or contact lenses	3	3	0	0
Nonscheduled cash allowances				
100 percent				
Eye examination	14	8	1	5
Eyeglasses or contact lenses	9	7	1	1
80 to 85 percent				
Eye examination	2	1	1	0
Eyeglasses or contact lenses	2	1	1	0
Scheduled cash allowances				
Eye examination	25	14	4	7
Eyeglasses[2]				
Frames	26	15	4	7
Single lenses	26	15	4	7
Bifocal lenses	14	8	2	4
Trifocal lenses	9	6	1	2
Contact lenses[3]	12	7	2	3

[1] Employees covered by dental plans having the same benefits for nonoffice and office employees.

[2] Includes some plans with combined allowance for eye examination and 1 pair of glasses (frame and single lenses). Plans that did not specify the specific type of lens were treated as covering all types.

[3] Includes plans with allowance for contact lenses not required for 20/70 vision acuity, frequently offered in lieu of all other benefits.

A relatively new method of cost control is "pretreatment" review, where the insurer reviews the proposed treatment and cost before agreeing to cover the cost. The pretreatment review requirement is usually for services estimated to exceed a specified amount. For example, in the Ford Motor Co.-United Auto Workers plan, when a course of treatment other than for emergency or preventive care is estimated to cost $125 or more, a "predetermination of benefits" form must be filed with the insurance carrier by the employee's dentist. The dentist describes the procedures required and estimates the charge. The insurance carrier notifies the employee and the dentist of the amounts payable, based on alternate and possibly less costly courses of treatment that may be appropriate in view of the benefits specified in the plan.

Vision care plans

Vision care benefits typically cover a narrow range of services—eye examinations, corrective lenses, and frames—but most plans cover all of these services. Of the 46 plans included in this analysis, 45 provided at least partial coverage for eyeglasses. (See table 3.) Three-fifths of the plans paid benefits according to a schedule of allowances which includes specific amounts for one examination and either one pair of glasses or contact lenses. Allowances for glasses are usually comprised of separate amounts for the frame and lenses, and allowances for lenses differ by type of lens—single vision, bifocal, trifocal, or contact lenses. For example, the Armour and Co.-Meat Cutters' plan for hourly employees allows $15 for one eye examination, $7 for the frame, $16 for single vision lenses, $20 for bifocal lenses, $24 for trifocal lenses, or $80 for contact lenses.

The remaining two-fifths of the vision care plans paid the full cost of at least an eye examination, either by paying the entire reasonable and customary charge for vision care services or by providing such services through a full-service plan.

Some plans provide higher allowances for eye examinations by ophthalmologists than by optometrists, and some cover contact lenses only if such lenses are required for 20/70 vision acuity. Other plans provide allowances for contact lenses not required for 20/70 vision acuity, in place of all other benefits, and some provide a lesser amount for contact lenses not necessary for 20/70 vision acuity. For example, the Associated General Contractors-Carpenters Union plan pays the full cost of contact lenses prescribed as necessary for 20/70 vision acuity, but pays only $55 if the lenses are prescribed for cosmetic or other reasons.

Cost controls, other than those provided by scheduled cash allowances and coinsurance features of nonscheduled allowances, consisted of: (1) limits on the frequency with which a benefit could be provided, (2) maximum benefits, and (3) deductibles. Nearly 9 of 10 plans stipulated that only one eye examination or one pair of glasses or contact lenses could be provided during a 1- or 2-year period; 1 of 5 plans specified maximum benefits that would be paid during a 1- or 2-year period; and only 2 plans required payment of deductibles.

The proportion of health plans with vision care coverage varied by employee group. More than one-third of the plans covering only nonoffice workers offered vision care, whereas fewer than one-fifth of those covering only office workers and one-fourth of those covering all employees had such benefits.

Vision care benefits were most often provided according to scheduled cash allowances, regardless of employee group covered. However, plans that had a more liberal payment structure that either provided full service or paid reasonable and customary charges were more common for nonoffice than for office employees.

The following tabulation shows the number of plans that are financed by employers or by employers and employees:

	Employer	*Employer and employee*
Active employees . . .	45	1
Retired employees:		
Under age 65	13	0
Age 65 or over . . .	11	0

All but one of the 46 vision care plans were fully financed by the employer. Thirteen plans, all employer financed, continued vision care for retired employees under age 65, and 11 plans continued such benefits to retirees over 65. With few exceptions, the plans provided retired employees the same benefits as active employees. ☐

FOOTNOTES

[1] The Bureau's periodic survey of health plans from 1974 to 1977 shows a 100-percent increase in employees covered by group health plans with dental coverage and a 50-percent increase in vision care. The Bureau's data for workers in metropolitan area establishments indicate an increase of 154 percent for plantworkers and an increase of nearly 200 percent for officeworkers covered by health plans with dental coverage. See Dorothy R. Kittner, "Changes in health plans reflect broader benefit coverage," *Monthly Labor Review*, September 1978, p. 57 and *Area Wage Surveys, Metropolitan Areas, United States, and Regional Summaries* (Bureau of Labor Statistics, various issues from 1974 to 1977).

[2] See *Digest of Selected Health and Insurance Plans, 1977–79* (Bureau of Labor Statistics, 1978) as amended by Supplement I, January 1979 and Supplement II, July 1979. Of the 148 health plans summarized in the digest, 71 plans covered nonoffice employees, 33 plans office employees, and 44 plans all employees (office and nonoffice).

[3] Employees in 3 health plans with dental benefits and in 10 health plans with vision care benefits had a choice of having benefits provided by a commercial insurance company, a nonprofit organization such as a dental or vision care service corporation, or health maintenance organization (HMO). In some cases the choice was between a plan with such benefits, usually an HMO, and one with no dental or vision benefits.

[4] The "nonoffice and office (all employees)" group include employees covered by dental plans having the same benefits for nonoffice and office employees.

[5] See Richard Ostuw, "Dental Plan Design," *Employee Benefits Journal*, Fall, Z977. Ostuw argues that liberal coverage of preventive care allows a greater portion of the covered group to qualify for benefits "thereby improving the degree of satisfaction with the plan by participants," and reducing the long-term cost of treatment.

Productivity growth below average in fabricated structural metals

The industry that shapes metal parts for buildings, bridges, and overpasses showed productivity setbacks in 1973–78, contributing to a 20-year average less than half that of the entire manufacturing sector

PHYLLIS FLOHR OTTO

Despite advances in technology, productivity growth in the fabricated structural metal industry has been only half that of all manufacturing industries, and in recent years output per employee hour has declined.

Fabricated structural metal plants convert mill shapes (primarily steel), by cutting, bending, welding, drilling, and other methods. Products include columns, joists, and trusses, which are used to build frameworks for buildings and bridges. Lesser quantities of products go to industries such as shipbuilding.

Output per employee hour in the industry rose at an average annual rate of 1.2 percent from 1958 to 1978.[1] (See chart 1 and table 1.) This is the result of an average annual increase of 2.2 percent in output and 1.0 percent in employee hours. Productivity growth for the entire manufacturing sector of the economy was 2.6 percent for the same period.

Productivity and output dropped during 1973–78. Productivity fell an average annual rate of 2.9 percent a year, and output by 3.9 percent. These losses were only partly offset by a 1.0-percent average annual drop in employee hours. The industry was particularly hard hit by the 1974–75 recession, and demand for bridge-building products was hurt by imports. Productivity in these years recorded the two largest declines in the industry, 5.8 percent in 1974 and 9.4 percent in 1975. A slight increase of 1.0 percent occurred in 1976, when employee hours fell more than output. However, the industry continued to record productivity declines after the recession, .3 percent in 1977 and an additional .2 percent in 1978.

Causes of declines

Productivity growth has been retarded by increased requirements for quality control and the made-to-order nature of goods produced in the industry, and by the lag in adjusting employment to changing output levels in this industry. Because of the high skill level of the work force, some employers attempt to retain employees during business downturns. When demand drops they tend to make lower bids for work, or bid on smaller jobs than they normally handle. This enables them to continue operating and retain their employees, and to cover some overhead costs in paying for capital equipment. However, this results in productivity de-

clines during cyclical downturns.

As in many other industries, short-term productivity changes in fabricated structural metal are closely associated with changes in output. Demand is directly affected by construction activity, which in turn is tied to cyclical fluctuations in the overall economy. The largest single market for the industry is industrial construction, which purchases about 24 percent of output. Commercial construction accounts for 20 percent; highway and street construction, 14 percent; public utilities construction, 13 percent; and educational building construction, 8 percent.[2] This means that at least 79 percent of the industry's goods are purchased by construction businesses. Because cyclical changes in the economy are heavily reflected in construction, output changes in the fabricated structural metal industry generally coincide with or lag slightly behind them.

The influence of cyclical fluctuations on productivity and output can be observed by comparing the 1958–73 period (a time of overall economic growth when productivity grew at an average annual rate of 2.3 percent a year) to the 1973–78 period (which included a major recession, when nonresidential construction was down significantly, and productivity declined at an average annual rate of 2.9 percent a year).

Advances during 1958–73

The 2.3-percent rate of growth in productivity during 1958–73 occurred while output in the industry was rising by 4.0 percent a year and employee hours by 1.6 percent. Increases in productivity during this period ranged from 1.2 percent in 1964 to 5.3 percent in 1971. Productivity declined only three times during the 15-year period. In 1959, it fell 2.1 percent in response to an 11.2-percent decline in output and a 9.3-percent decline in employee hours. New construction of industrial buildings dropped 10.6 percent, and public utilities, 5.8 percent.[3] In contrast, the two other declines in productivity during the 1958–73 period, 2.2 percent in 1966 and 0.4 percent in 1969, occurred when employee hours rose more than output. A contributing factor was the shortage of skilled employees, particularly drafters and welders.[4]

The construction and fabricated structural metal industries prospered during the economic expansion which characterized most of the 1958–73 period. The few declines in output were between 1 and 2 percent except in 1959. Schools, colleges, and hospitals were being built at a rapid rate. Overall, construction of nonresidential buildings increased at a rate of 3.7 percent a year. Continuous data are not available for all of the subcategories, but construction of industrial buildings rose at an average annual rate of 6.2 percent from 1958 to 1964. Construction by public utilities expanded at a rate of 6.1 percent a year during 1958–73. It was also during this time that most of the interstate highway system was constructed, increasing the demand for metal to erect bridges and overpasses.

Adding to the strong demand during the 1958–73 period was the industry's ability to compete with alternative construction materials by introducing new products. For example, the introduction of high strength steel in the early 1960's enabled the industry to combat the competition from concrete manufacturers in the high-rise buildings market. High strength steel is stronger and lighter than conventional steel, resulting in lower overall building costs in some cases. Another new product was weathering steel, which develops a protective patina when exposed to the atmosphere, resulting in lower maintenance costs.

Slow employment growth

The industry employed 98,500 persons in 1977, including 72,000 production workers. Employment rose at an average annual rate of 1.1 percent from 1958 to 1978, slightly faster than the 1.0 percent rate in work hours. There has been a small reduction in average annual hours worked per employee.

Employment in the industry peaked at 107,500 in 1967 and has been generally declining since, reflecting

Table 1. Productivity and related indexes for fabricated structural metals, 1958–78

[1967 = 100]

the declining output of recent years. In the autumn of 1977, most plants were operating at no more than 60 percent of capacity. During that year, many firms went out of business.[5]

Production workers have consistently accounted for 74 to 75 percent of the employees in the industry. Therefore, the trend in output per production worker hour, 1.3 percent, is similar to that for all employee hours. A 1974 survey showed 75 percent of production workers in the industry scheduled to work 40 hours a week, with the remainder scheduled for additional time. None was scheduled to work fewer than 40 hours. However, crews often work either more or less than the scheduled number of hours.[6]

Most production workers are in skilled occupations, many doing highly judgmental work requiring specialized knowledge such as welding, layout, and inspection. Workers earn high wages reflecting these skills. During 1958–78, average hourly earnings were about 7 percent higher than for all manufacturing industries. Many of these employees, in occupations such as crane operator, welder, and layout worker, have skills which can be transferred to other heavy industries; if they are laid off their return may depend on the proximity of other heavy industry in the area.[7]

The industry also requires many structural drafters and engineers to design shop drawings; architectural drawings are not completely detailed. Many details must be filled in before construction begins. These employees make up about 10 percent of the work force.[8]

The fabricated structural metal industry consists mainly of many small establishments serving primarily local markets. In 1972, 50 percent of the shops in the industry had fewer than 20 employees, and 30 percent employed between 20 and 49 persons. The industry includes plants owned by major steel companies or their subsidiaries, which fabricate metal for their own use.

Few projects are bid on the national market for fabricated structural metal. A few large fabricators sell within a region, but most establishments service smaller local markets within about 200 miles of their plants. Transporting the finished product is costly, so most fabricators are in densely populated areas, near major construction sites.

Technology and capital expenditures

From 1958 to 1977, growth in capital expenditures per employee in the fabricated structural metal industry averaged 7.8 percent a year as compared to 8.0 percent for all manufacturing industries. Most of the capital expenditure has been in the largest firms. Bidding on major projects and maintaining a sizable work force, they are the buyers of heavy or sophisticated equipment.

The most important new technological development in the industry is the automatic beam line which has been an important aid to productivity gains. Beam handling can be a time-consuming and costly process in the shop. Some studies show that using the old technology, a beam is lifted by a crane at least 16 times while being moved between work stations.[9] Each lift requires the use of at least two employees. The introduction of automatic beam lines eliminated much of this burden. The automatic lines move beams to various work stations along roller conveyors, where automatic drilling, punching, and cutting operations occur. The conveyors can be used with an automatic gauge. This is a block which moves along underneath the conveyor and stops at a point designated by the operator. The block moves between the rollers to stop the beam. This provides an accurate gauge for the metal and automatically positions the beam at the point where it is to be worked on. Beams can be moved automatically from one line to another by a set of bars which move between the rollers and flip the metal onto the next conveyor.

This process has facilitated the use of automatic equipment for cutting, punching, drilling, and welding. Usually, the layout of the plant is altered to accommodate beam handling equipment, minimizing the number of times, and the distances the metal must be moved.

The welding process has become increasingly automated, allowing increased use of shop welding without a proportionate increase in the number of welders. In 1964, 24.8 percent of the production workers in the industry were hand welders, and 3.4 percent machine welders.[10] By 1974, the proportion of hand welders had fallen to 19.6 percent and that of machine welders had grown to 7.0 percent.[11] New methods, allowing for faster deposition of the weld metal, have speeded the process.

Computers and automation

The increasing use of computers has resulted in additional automation. Computers are used to handle inventories, payroll, and clerical functions. One of the most important applications has been in work scheduling. Fabricated structural steel must be delivered to the construction site on a workflow basis. The fabricator must match the needs of the contractor by arranging a schedule which makes optimum use of available resources. The computer is also used in drafting and designing work.

There are numerous applications for numerically controlled machinery in the manufacture of fabricated structural metal. Some machines are able to do the jobs of skilled layout workers. The machinery can punch holes in proper relationship to the sides and end pieces of sections, automatically compensating for metal which is not perfectly squared. It has also been used for drilling, cutting, and welding tasks in the workplace.

Another technological advance in the industry is the cold cut saw for cutting structural shapes. This circular saw is continuously bathed in oil as it rotates, and increases productivity in two ways: cold cutting is faster than the friction sawing it replaces, and leaves fewer burrs to be removed. Cold cut saws are also quieter than friction saws.

Quality control has always been important work in the fabricated structural metal industry. However, more employee-hours are spent on quality control now than in the past; contractors and designers are demanding closer tolerances, and because labor costs have increased faster at the construction site than in the plant, it is cheaper to have this work done in the plant.

There have been some technological improvements in quality control. The job has become far more sophisticated, particularly in weld inspection. Electronic testing of welds has become much easier; portable weld testers are now available.

The growth in modular construction has led to further investment in new capital equipment. The allowable variance of dimensional tolerance for modular construction is tighter than in other types of buildings. Mechanization is one way of tightening tolerances for this kind of construction.

More stringent safety standards resulted in some capital expenditures being made for safety equipment and noise protection. This has provided employees with a safer work environment and may have reduced expenditures on other capital equipment.

Slow growth probable

Productivity growth in the fabricated structural metal industry probably will not resume until output picks up. Industrial construction, the major market for the industry, did not increase until mid-1978. Much of the activity until now has involved rehabilitation of existing structures. This is relatively inexpensive but does not benefit the industry. Neither does the move by corporations toward rural and suburban areas. Because land in these areas is cheaper, many of the office buildings are low structures which use little or no structural metal.

Regardless of the anticipated recovery in nonresidential construction, there are good signs for the future of the fabricated structural metal industry. Oil companies are placing orders for metal to construct offshore drilling platforms. These orders call for delivery in the early 1980's. Estimates have been made that more than 100,000 bridges in this country are in need of replacement.[12] Although replacement is not being funded now, it could be a good long-range market for the industry.

Productivity growth will probably remain lower than the all-manufacturing average. The industry is tied to individualized, custom work. This prevents long runs of similar products, and the economies which accompany them. Work must continue on a flow basis, benefiting and accommodating the contractor rather than the manufacturer. Further, stringent quality control and testing will continue to be necessary. ☐

——*FOOTNOTES*——

[1] Average annual rates of change are based on the linear least squares trends of the logarithms of the index numbers. The fabricated structural metal industry is designated industry 3441 in the Standard Industrial Classification Manual, 1972 Edition, issued by the Office of Management and Budget. The industry comprises establishments primarily engaged in manufacturing fabricated iron and steel or other metal for structural purposes, such as bridges, buildings, and sections for ships, boats, and barges. A technical note describing the indexes is available upon request. The indexes for this industry will be updated and included in the annual Bureau of Labor Statistics Bulletin, *Productivity Indexes for Selected Industries.*

APPENDIX: Measurement techniques and limitations

The productivity indexes in this study measure the change over time in industry output per unit of labor input. They do not measure the specific contribution of labor, but reflect the influence of many factors such as technology, capital investment, and managerial skills, as well as the skill and effort of the work force.

The output index is based on value of shipments data adjusted for inventory change, published by the Bureau of the Census. Detailed data from the Census of Manufactures for 1958, 1963, 1967, and 1972 were used to derive benchmark indexes, to which the annual indexes for intervening years, based on the Annual Survey of Manufactures, were adjusted. The value of shipments of the various product classes were adjusted for price changes by appropriate Producer Price Indexes to derive a real output measure. These, in turn, were combined with employee hour weights to derive the overall output measure. Employment and employee hour indexes were derived from census data. Employees and employee hours are considered homogeneous and additive, and thus do not reflect changes in the qualitative aspects of labor, such as skill and experience of persons constituting the aggregate.

Data on the quantities of goods produced by the fabricated structural metal industry are not complete. Real output, therefore, was estimated on the basis of a deflated value technique. That is, changes in the price levels of the current dollar value of production were removed by means of appropriate price indexes. Because an adjustment for changing price levels usually lowers the dollar value, such a series is referred to as a deflated value measure. In an industry such as the fabricated structural metal industry, where the raw material may differ from one product to the next, this technique may result in some bias in the measure. However, this bias is minimal.

To combine segments of the output measure, employee hour weights relating to the individual segments were used. This technique was used at various levels of subaggregation for the variety of products manufactured by this industry. These procedures result in a final output index that is conceptually close to the preferred output measure.

Indexes of output per employee hour relate total output to one input labor time. The indexes do not measure the specific contribution of labor, capital, or any other single factor. Rather, they reflect the joint effects of such factors as changes in technology, capital investment, capacity utilization, shop design and layout, skill and effort of the work force, managerial ability, and labor-management relations.

Conference Papers

Labor force activity of married women as a response to changing jobless rates

OLIVIA S. MITCHELL

For married women, the bulk of cross-sectional literature appears to indicate that the net effect of local unemployment rates on participation is a negative one.[1] Early time-series studies also showed a small procyclical labor force response of married women,[2] but recent papers seem to reveal a counter-cyclical pattern.[3]

Resolution of this empirical paradox is of interest, because a prevalent "discouraged worker" effect suggests that economic prosperity will simply draw more females into the labor force without decreasing observed unemployment rates substantially. On the other hand, if women enter the labor force in response to high local unemployment, and then withdraw in more prosperous periods, policies to stimulate economic growth will reduce the overall unemployment rate more rapidly than expected. Jacob Mincer's discussion of the issue suggests that "the findings in the cross-section analysis constitute evidence largely in favor of a hypothesis that prolonged depressed employment conditions in an area tend to shrink the area's labor force rates."[4] The implication is that cross-sectional behavior reflects primarily a long-run response to permanent unemployment faced in each labor market, while time-series data are more likely to reveal participation response to cyclical changes. However, no previous attempts to resolve this question have been able to distinguish effectively between the behavioral responses to short and long-run labor market conditions.

These long-term differences between labor markets are probably the result of various characteristics of labor markets which are difficult to measure with accuracy. However, if these factors are correlated with included explanatory variables in labor force participation models, coefficient estimates for other variables will be biased. For example, wages and employment rates are probably correlated with seasonal and industrial employment patterns specific to each labor market, educational systems vary with location, job and pay structures depend on the power of unions and discriminatory customs, and the manner in which social/welfare programs are administered determine the environment in which labor supply decisions are made. These factors cannot be satisfactorily quantified, but controls are required in order to obtain unbiased estimates of the explanatory variables of interest.

I have examined both cross-section and time-series results for a panel of data on major U.S. cities over the period 1968–75. The labor force participation equation is similar to those estimated by other researchers, but in accordance with the underlying hypothesis in this paper, results for separate cities and separate years are estimated. As Mincer predicted, time-series behavior differs from that in the cross section. The novelty of the approach is that an overall response in pooled data can also be examined. Here the results are found to depend on the way city-specific structural effects are modeled.

Olivia S. Mitchell is assistant professor of labor economics at Cornell University. Her full IRRA paper is entitled "The Cyclical Responsiveness of Married Females' Labor Supply: Added and Discouraged Worker Effects."

Data and estimation

Data from the March Current Population Survey (CPS) are available for the years 1968 through 1975. By grouping observations on married women (spouse present) living in the 19 locations identified by the CPS in each year, I obtained a panel of cross-section time-series data for the largest urban labor markets in the nation. Aggregation of micro data in this way reduces errors in measurement and variations in tastes, and permits the appending of area-specific unemployment measures obtained from *Employment and Earnings* and the *Economic Report of the President.*[5] All nominal variables are deflated by a consumer price index which takes into account price variations across Standard Metropolitan Statistical Areas over the 8-year period.[6]

One problem with the CPS, as with most data sets, is that wages are not observed for many sample respondents. Here, two approaches are taken. First, an educational attainment term is used as one proxy for wages. Second, a wage rate applicable to full-time female workers is imputed to all women based on location of residence.

When a full-time worker wage rate is used to control for offered wages in each labor market, cross-sectional patterns within most years show a negative relationship between unemployment and participation rates which suggest a net discouraged worker effect. However, regressions for each urban area over 8 years indicate that rising local unemployment rates induce female participation. This is consistent with a net added worker response; and, in many cases, the correlation is statistically significant. Analysis of pooled data without city terms indicates an insignificant participation response; however, when the pooled model is expanded to include city-specific intercepts, the female participation response to local joblessness is positive and highly significant. Thus, a predominant added worker effect is observed when structural between-city differences are incorporated.

As a final check on the differential impact of cyclical and long-term area unemployment, I examined female participation responses to the difference between average and current local unemployment over time. Results from pooled data indicate unambiguously that when local unemployment exceeds the 8-year city average, female participation rises; conversely, participation rates decline when local joblessness falls below the long-term average.[7] This net added worker effect is statistically significant whether or not city-specific intercepts are included, which supports the notion that deviations from long-term conditions are better predictors of cyclical behavior than are the current unemployment rates. It should be noted that even in this case a majority of city terms differs significantly from zero, suggesting that these factors pick up persistent patterns of behavior in addition to the long-term unemployment conditions.[8]

THE APPARENT PARADOX between cross-section and time-series female participation responses to unemployment reported in the literature is thus resolved when city-specific characteristics first alluded to by Mincer are explicitly controlled. Though further research is required to identify the information summarized in these city-specific intercepts, theoretical arguments indicate that they should be incorporated. When they are not, static year-by-year relationships between cities show that a low female participation rate is associated with depressed business conditions. However, the relationship over time within a city or within a group of cities is positive on net, if long-term structural differences are controlled. This added worker response may be more relevant for policymakers concerned with predicting labor force cyclical sensitivity, rather than estimating a mixture of long and short-run responses to unemployment in each labor market. □

[5] Bureau of Labor Statistics, Bulletin 1370–12, 1974, and Office of Management and Budget, *Economic Report of the President,* 1975, Washington.

[6] This was derived from intra-SMSA cost of living indexes published annually in the *Monthly Labor Review.*

[7] The variable is defined as the difference between unemployment in each city averaged over the 8 years and the current unemployment rate in that city. Without city intercepts the coefficient on this term is –.006 (with a t statistic of 2.57); with city intercepts the coefficient is –.007 (with a t statistic of 4.23).

[8] Further evidence supporting the dominance of an added worker effect appears in analysis of the underlying micro cross-section data from the CPS. A probit regression of wives' participation on economic and demographic variables similar to those used above also produces a positive unemployment coefficient when city-specific intercepts are used, but a negative coefficient when city-specific terms are excluded. See Olivia Mitchell, "The Labor Supply of Nonmarried Women," paper presented at the Econometric Society meetings in Atlanta, GA, Dec. 28–30, 1979.

Unionism's effect on faculty pay: handicapping the available data

MARTIN J. MORAND AND DONALD S. MCPHERSON

One of the unanticipated outcomes of collective bargaining in higher education has been the creation of a new industry—academic studies of academic unionism. The implications of faculty bargaining for such traditional concerns as academic freedom, collegiality, governance, and similar abstruse subjects have attracted speculation and study. Articles published in these areas represent no more than individual theorizing or rely on data which are no more than a collection of individual opinions. In contrast, those scholars who focus on the compensation question—how unionism relates to wages and fringes—would seem to have the advantage of a wealth of objective data.

All interested academicians are familiar with the American Association of University Professors (AAUP) "Annual Report on the Economic Status of the Profession." It is convenient, predates collective bargaining, covers unionized and unorganized institutions, and serves as the basic statistical resource for most research. AAUP edits, interprets, and publishes data that, since 1976, have been gathered exclusively by the National Center for Education Statistics (NCES) through the Higher Education General Information Surveys (HEGIS). Yet, these compensation studies have reached sharply contradictory conclusions which lead to lengthy and learned argument over the relative advantages of matched pairs versus multiple regression. The fault lies less in the statistical methodology than in the assumption that the statistics are complete, relevant, and accurate enough to reach meaningful conclusions on the relationship between unionism and wages, hours, and working conditions in academe.

We acknowledge our own bias. We are active members of the Association of Pennsylvania State College and University Faculties (APSCUF, affiliated with AAUP and American Federation of Teachers, AFL-CIO), the union of the Pennsylvania State College and University (PSCU) system where we work. As beneficiaries of faculty unionism, we approach studies which report a negative or null effect of collective bargaining on faculty compensation with skepticism. If the impact be so slight, why does management protest so much? Or, as Brown and Stone wonder, because faculty unions have not been associated with general economic gains and union dues are substantial, what explains the rapid growth of faculty unionism?[2] Further, because it is easier to decertify than to organize (because administrators seldom fight to keep unions) why have faculties which come to unionism with such misgivings not repudiated their unions?

Our interest and suspicions grew out of the contradictions between our own experience and published reports on our system. For example, the 1975 AAUP report showed an increase of over $3,000 per faculty member in our system. It caused consternation in Pennsylvania political circles, showing that the PSCU had shot ahead of faculty compensation at the prestigious University of Pittsburgh. But we knew that our across-the-board increase for that year was 4 percent, or about $1,000. Investigation revealed that almost two-thirds of the reported *raise*, about $2,000, was actually the result of a *reduction* in the employer's cost for pensions.

This is one of several conundrums which led us to suspect first the statistics and then the statisticians. The explanation of the contradiction between what AAUP reported and what we observed is simple and revealing. In order to improve benefit packages generally and pension mobility particularly, AAUP counts only those employer contributions that become vested (in the faculty member) within 5 years. The State contributions to the retirement system never before "counted" because in Pennsylvania pensions became vested only after 10 years.

But in 1975 the faculty union negotiated an optional retirement system with immediate vesting. Although *few* faculty chose the option, once immediate vesting became available, the institution was credited under AAUP rules as if *all* were covered. Our university saves thousands of dollars each year on faculty who opt out of the State system because it is now charging double to catch up on prior years of underfunding. In the very year the union's negotiated cost saving was implemented, the university appeared to be paying a large increase for faculty retirement benefits.

These apparent discrepancies led us first to suspect that the fault lay with AAUP. However, after extensive dialogue with AAUP's director of research, Maryse Eymonerie, we became convinced that the numbers themselves are not the villains. She shared with us, as she told us she had with previous researchers, her perceptions of the pitfalls inherent in unsophisticated application of published figures. Our own findings on data deficiencies are organized under four headings.

Missing data

Some data are missing; some just missed. HEGIS tapes contain information not summarized on AAUP charts. The tapes include all employer payments for

---

Martin J. Morand is Director, Center for the Study of Labor Relations, and Donald S. McPherson is Chairperson, Department of Labor Relations, Indiana University of Pennsylvania. Their full IRRA paper is entitled "Back to Basics: A Call for Accuracy in Research on Collective Bargaining's Effect on Faculty Compensation."

pensions including those, primarily in the public sector, which do not vest within 5 years. HEGIS tapes also include all employer costs for housing subsidies and tuition benefits. AAUP does not include these benefits unless a cash option is available. Jerome Staller's study of community colleges uses these raw data. We do not know whether counting these benefits influenced his finding that "unionization has raised fringe benefits nearly 80 percent over those prevailing in nonunion colleges."[3] But Staller was the first scholar in the field to insist that salaries *and* fringes *and* hours—or their analogue, workload—because they could either be improved in tandem or traded against each other, must be examined separately and severally in any study of total compensation. Despite his warning and despite the fact that the literature makes it clear that workload is a major issue at the bargaining table,[4] only one other compensation study that we know of deals with it.[5]

The complexity of defining and measuring workload, the difficulty of measuring salaries outside the base year and the danger of relying on AAUP tables as the only information source are all illustrated in a single example. Pennsylvania State University (not to be confused, as it was by one researcher, with PSCU) has transferred hundreds of faculty from 48-week to 36-week contracts since 1974. They maintained their full salary and were expected to maintain "the same workload (particularly teaching) and quality standards." Does this represent a 25 percent increase in salary? It is reported as such to AAUP. Is this a reduction in workload? If one views workload as time work, yes, as piecework, no. The faculty member who volunteers to accept this offer must agree to forgo across-the-board raises for 2 years. Why do they accept? In many cases because they can now earn extra income during the newly freed 12 weeks—income sometimes paid from the same grants they work under during the 36-week payroll period.

Other significant omissions from available salary data important to studies of collective bargaining include: retroactive salary payments, improved summer contracts, compensation for co-curricular duties, stipends for chairpersons, released time for consulting and grant income which supplements salaries. The contract at the City University of New York system provides over $3.5 million annually for research and fellowship awards. Our own union negotiated a $500,000 trust which funds educational expenses, research, and travel.

Eymonerie listed benefits which are omitted from the various surveys, some of which have a significant collective bargaining related impact. Her examples include: "office space, secretarial assistance, library privileges, laboratory and computer facilities, travel and membership fees to professional organizations, parking, meals, and sabbatical leave."[6] Our records add: professional liability insurance; paid leaves for illness, parenting and education; reduced interest loans; and wholesale costs for purchases of insurance, autos, appliances. One contract even guarantees the right to collect a cord of wood on campus.

It is clear that data currently missing on changes in workload, on extra salaries, and on missing benefits must be collected and considered in any effort to evaluate accurately the impact of faculty unionism.

Misleading data

Academicians' faith in the salutary effects of grading on a curve to encourage improved performance leads AAUP to continue to report legislated benefits such as social security. It hopes to encourage all States to make coverage mandatory. Because salaries subject to social security taxes have a ceiling, this item is reflected in the reports as a greater "fringe benefit as a percent of salary"[7] at campuses with lower salaries. Thus, institutions which pay less get higher "marks" in the fringe column.

Unemployment compensation replicates the social security problem and adds a peculiar, collective bargaining related, distortion of its own. Institutions are often on a pay-as-you-go basis with unemployment compensation—the more layoffs, the more payout, the more chargebacks. Many unions have succeeded in blocking mass retrenchments and reducing individual dismissals. This faculty benefit, when reflected in lower unemployment compensation costs, appears as a lower fringe and thus less total compensation rating on the charts.

An accurate evaluation of legislated fringe benefits as an obviously important part of compensation must, in any case, deal openly with these problems of misleading data.

Misinterpreted data

Definitions and instructions used in surveys are ignored by respondents and researchers alike. "Instructional faculty" is the group purportedly being counted, and faculty researchers mistakenly assume we all know what that means. But collective bargaining and its concommitant, unit determination, have changed the perception, if not the definition, of the term. Studies which compare the pre-bargaining 1960's with the post-bargaining 1970's are often comparing oranges and lemons.

For example, our union represents two bargaining units—teaching faculty and administrative faculty. But the teaching unit includes, among others, librarians, coaches, counselors, student-teacher supervisors, athletic directors, equal-opportunity-in-sports coordinators and department chairpersons. All or part of their salaries ought to be excluded from the reports. Some campuses, particularly where the person responding has been filling out HEGIS questionnaires since the pre-bargaining days, do exclude them. Others, understandably, find the numbers to fill in on the form by punching a button on the computer which is programmed by bargaining unit—including all these persons and their *total* instructional and administrative salaries. We came across this problem when we observed campuses reporting salaries higher than the maximum contained in the contractual salary schedule because they were including these administrative payments. Although textual exegisis is not our preferred procedure for understanding the dynamics of collective bargaining, a look at the contract while looking at the report might alert researchers to problems they now miss.

Mistakes in data

Most of the data error we identify is in the Pennsylvania reports, presumably because we are more familiar with the facts and alert to the problems. But we have no reason to believe the situation is different elsewhere. Indeed, Professor James Begin of Rutgers finds problems with HEGIS data in his studies of collective bargaining in New Jersey community colleges, particularly because of failure to capture retroactive pay increases.[8] While these occur frequently in collective negotiations they are seldom granted to the unorganized.

Scanning the charts and checking the contracts in the PSCU reveals that for 1973–74 Cheyney State College reports a 21-percent increase for associate professors, and Edinboro State College shows 23 percent for instructors. With a 5-percent across-the-board increase in September '73 and an additional 5 percent in January '74, no arithmetic combination of additional increases such as merit, promotion or increment could have led to the average increases reported. They were far in excess of amounts published for other ranks at these colleges and for any ranks at other PSCU colleges. We believe reporting error is inherent in the data collection system and not unique to the PSCU.

BACK TO BASICS in measuring the impact of unionism on faculty compensation means more than cleaning up the economic data. The HEGIS data are better than those available for most industries. The best of data will only be understood if examined in the context of institutional research, which itself takes into account the insights of the behavioral sciences. Campus unionism presents a unique opportunity for collective bargaining researchers to examine theory in practice. ☐

Hospital managers' perception of the impact of unionization

CHARLES MAXEY

During the past decade there has been substantial growth in the number of formal union-management relationships in the U.S. hospital industry.[1] As in other sectors where vital human services are an important employer "product," the growth of hospital employee unionism has been a controversial development. Industry spokespersons and other observers have expressed concern over the impact of collective bargaining on the financial vitality of the industry, and on the ability of

---

Charles Maxey is assistant professor of organization behavior at the University of Southern California. His full IRRA paper is entitled "Organizational Consequences of Collective Bargaining: A Study of Some Noneconomic Dimensions of Union Impact."

the hospitals to maintain quality health care services. The general research issue which arises, then, concerns the impact of unionization and collective bargaining on the employer as an organization, and on organizational performance.

Trade unions may affect employers in numerous ways that have implications for how the organization performs. Strikes and other job actions provide obvious short-run examples. But the research literature suggests that longer term changes in organizational structure and process are also important. Examples of such organizational impact are: effects on the content and execution of human resource management policy, impact on the structure of decisionmaking within management, and impact on the attitudes and behavior of both managers and nonsupervisory employees.[2] This paper presents some general and preliminary findings from a study intended to assess such organizational changes in unionized hospitals.[3] A number of areas of union impact will be reported on in brief, summary form, but particular attention will be given to effects on the ability of the employer to provide quality patient care, and on other organizational dimensions that might reasonably be expected to influence overall performance—the role of hospital management, and the attitudes and behavior of unionized, nonprofessional employees.

The findings reported here are based on hospital managers' assessment of the magnitude and direction (positive or negative) of union impact on their own organizations. Perceptual data of this kind are of considerable value because they reflect the understandings of those intimately involved in the labor-management relations, where differences of values and goals between the parties can generally be assumed, and varying assessments of the nature of union impact on the employer can be expected.

A second purpose of this study was to present some preliminary results on the development of an explanatory or interpretive framework for the managerial perceptions reported. The model, presented in the full version of this paper, hypothesizes systematic relationships among managers' perceptions of a number of dimensions of union impact.

The data

Data for the study were collected through administration of written survey questionnaires to managers employed in 36 unionized hospitals located in 6 major U.S. cities. Cities were selected to represent a variety of bargaining structures and climates. Within cities, hospitals were chosen to provide variety in terms of organizational size, ownership, pattern of employee representations, and managerial philosophy. Individual managers were selected on the basis of position (senior administrator, personnel/industrial relations officer, supervisory physician, nursing administrator, support service department head), and knowledge of the union-management relationship. In all, 292 managers participated in the survey.

The survey instrument used Likert-type response scales to obtain managers' views of the nature of the union-management relationship, and the impact of unionization and collective bargaining on the hospital; 79 impact questions were included. Respondents made assessments of both the *magnitude* of union impact, and its *direction* (positive or negative as seen from the per-

Table 1. Hospital managers' perceptions of the strength and direction of union impact in selected areas

Impact areas	Mean response[1]	Percent negative		No impact	Percent positive	
		Strong	Weak		Weak	Strong
General						
Centralized policy making	4.04	7.7	3.5	11.6	32.0	45.2
Wage levels (union employees)	3.53	24.7	8.9	2.6	16.6	47.2
Ability to retain employees	3.52	8.2	11.3	25.7	30.0	24.8
Overall quality of care	2.86	10.9	22.3	42.0	19.7	5.0
Productivity of employees	2.80	19.9	23.5	26.3	17.5	12.7
Financial standing of hospital	2.65	39.8	16.6	6.2	13.3	24.1
Hospital management						
Overall quality of management	3.70	5.8	5.8	27.4	35.1	25.9
Ability to run hospital effectively	2.97	15.8	25.8	19.2	23.8	15.4
Authority of supervisors	2.93	22.8	33.6	9.3	26.6	17.8
Employee attitudes and behavior						
Interest in long-term employment	3.62	5.4	9.3	28.3	32.2	24.8
Turnover	3.30	7.7	15.1	34.7	25.1	17.4
Interest in promotion	3.28	8.2	14.0	31.1	34.6	12.1
Morale	3.12	11.5	23.0	20.3	33.0	12.3
Absenteeism	2.79	17.6	26.1	25.3	21.8	9.2
Commitment to goals of hospital	2.75	15.6	25.8	33.8	17.1	7.6
Willingness to perform extra work	2.40	30.3	27.3	21.1	12.7	7.6

[1] Items are scaled: 1 = Strong Negative Impact; 2 = Weak Negative Impact; 3 = No Impact; 4 = Weak Positive Impact; 5 = Strong Positive Impact. Total number of responses was 292.

spective of the hospital). Magnitude was measured on a 5 point scale, and direction on a 3 point scale (+, 0, −).[4]

Table 1 displays some of the survey results. On the basis of the aggregated results (some of which are not reported in the table for space reasons), the following generalizations are warranted:

Economic impact (wage and benefit levels) was seen as substantial. Managers reported positive effects in terms of increased stability of employment and an improved competitive position in local labor markets. On the other hand, the overall financial standing of the hospitals was seen to have been adversely affected.

Within management, decision and policy making had become more centralized, with senior administrators and personnel/industrial relations specialists assuming an expanded role. Employee relations policies were seen to have become more formal, more similar across organization subunits, and applied with greater consistency.

Departmental managers and supervisors were seen to be spending more time in direct supervision and in attending to matters of discipline. The quality of supervision and management were felt to have improved, but the difficulty of the supervisor's job had increased. Similarly, the overall ability of management to run the hospital effectively was seen to have been diminished.

Managers perceived the attitudinal and behavioral responses of nonsupervisory employees to have fallen along two interrelated dimensions. Managers believed that the desirability of the hospital as a place of employment had increased as reflected in both employee attitudes (morale, interest in long-term employment, interest in promotion) and behaviors (reduced turnover). However, performance-related changes were viewed negatively; respondents reported decreased commitment (to the mission of the hospital and to patient care as a goal) and poorer work performance (increased absenteeism, decreased willingness to perform, decreased productivity.) The overall pattern in the aggregated data suggests managerial perception of an increased "instrumentalism" on the part of unionized employees.[5]

Finally, the quality of patient care, a significant dimension of overall organizational performance, was seen to have been negatively affected, although the size of the effect is not great on average, and there is considerable disparity among respondents as to both the strength and direction of the effect. ☐

——*FOOTNOTES*——

Data collected by the American Hospital Association indicate that between 1967 and 1977 the number of U.S. hospitals with at least one formal union-management agreement increased from 6.7 percent to about 25 percent.

[2] For example, see S. H. Slichter, J. D. Healy, and E. R. Livernash, *The Impact of Collective Bargaining on Management* (Washington, D.C., The Brookings Institution, 1960).

Two approaches to the mediator's role

DEBORAH M. KOLB

The differing roles mediators play, "deal maker" or "orchestrator," reflect respective common sense theories about how disputes between the parties get resolved.[1] Mediators from a State agency, who generally want to make a deal, believe that such a deal, if achieved, results from their knowledge of the components of a reasonable settlement (and, by implication, the parties' ignorance of such components), combined with their ability to persuade the parties to accept such a "reasonable" settlement. Federal mediators, however, prefer a settlement to be achieved by the parties themselves. By orchestrating a full exploration of their differences with some assistance and "injections of reality," Federal mediators believe that parties generally will be able to resolve their own differences.[2]

These theories held by mediators about how disputes get resolved emerge from the roles the mediators attribute to the other parties in the process. The State mediators believe that they need to put together a deal because the other actors in the process—the union and management committees—lack the expertise to do it themselves. The inexperience of the bargaining committees is readily apparent to the mediator. Committees, particularly those on the union side, come to mediation with long lists of demands—demands which are often unrealistic in the estimation of the mediator. Inexperienced committees get "wedded" to their positions and are therefore exceedingly reluctant to lower their sights

---

Deborah M. Kolb is assistant professor of organization behavior and industrial relations at Simmons College. Her full IRRA paper is entitled "Roles and Strategies of Labor Mediators."

or to delegate the authority to the negotiators they hire (who have the expertise to negotiate more effectively). Committees on the management side, often made up of politically elected representatives, are likewise described as inexperienced. They adopt exceedingly conservative positions and adhere to these positions tenaciously.[3]

Federal mediators, interestingly, describe the union negotiating committees they encounter in the private sector in much the same way as do the State mediators. These committees are inexperienced: they come unprepared to mediation with too many demands, many of which are unrealistic and, because of their inexperience, only make changes reluctantly. The management committees the Federal mediators work with are often as inexperienced as the union committees, but the inexperience is manifested differently. Management committees tend to overprepare, and to adopt bottom line positions early in the negotiations that leaves little room for exploring options. However, as opposed to the union committees which have a democratic structure and require a majority (if not a consensus) to make a move, the management committees have a hierarchical decisionmaking structure. The process of generating movement, therefore, differs between the two types of committees.

In most of the cases studied, negotiating committees on both sides had chief spokesmen, most of whom were professional negotiators. These professionals, because of their experience and frequent encounters with mediators, are called "pros." For the most part, pros are either labor relations attorneys or business agents from the union. Both State and Federal mediators had pros on their cases with approximately the same frequency, but the expectations about how these pros would act in their relationships with their committees, with the mediator, and with each other differed.

The State mediators looked to the pros to help them make a deal, a deal the committees, because of their inexperience, presumably would be unable to reach themselves. When working with two pros, the State mediators expected that most of the mediation would be conducted in off-the-record meetings. As a team, the pros and the mediator, both knowledgeable in the prerequisites of a reasonable settlement, could come gradually to an agreement. During the case, the mediator would then, in concert with the pros, "sell" the agreed upon package to the respective committees. With just one pro on the scene, the mediator had assistance on one side in the form of insights into the committee's behavior and the pro's assessment of "what it would take" to get a settlement—the bottom line. But the pros did not always function in this way. The problem from the State mediator's viewpoint is that the committees, because they are inexperienced, control their spokesmen in such a way that their ability to make an off-the-record deal may be severely circumscribed. When this occurs, the pro isn't acting like a pro. According to one State mediator,

> There are pros, but it's not just his experience. Only if they have the authority to bargain, are they true pros. And for a true pro, if he doesn't have the authority, he'll grab it, he'll demand it as a condition of his continued employment.

State mediators often found that their expectations about what the pros would do went unfulfilled. Many pros, according to the State mediators, acted unprolike during a case. And the mediators' explanation for this behavior rested with the inexperienced committees. They were so inexperienced that they controlled the pro too tightly, and thus the effect of having a pro at all was negated. This inexperience of the committees (manifested in their tight control and the presence of pros who often did not act like pros) reaffirmed the mediator's sense of his role. He needed to "educate" the parties about the realities of mediation, which he did by demonstrating the elements of a reasonable settlement (his deal).

To the Federal mediator, the pro is an experienced, knowledgeable, and effective negotiator who is as well acquainted with the elements of a reasonable package and often better informed about the local character of the issues in dispute than the mediator. Though the pros and the mediator would be capable of reaching a reasonable settlement, the acceptance of such a settlement rests with the committees. Thus it is the pros, each working with his respective committee, who, through the ever narrowing exchange of proposals, move a committee toward a settlement. With the hierarchical management committee, the pro's advice was more likely to be heeded. But with the inexperienced union committee, the process was likely to be long and arduous, often requiring more assistance from the mediator.

For the Federal mediator, the mark of the true pro is not that he grabs authority but that he acts like a "closer." A closer is a pro who, based on his experience and knowledge, uses that expertise to move his committee by suggesting alternative options for a settlement when negotiations have reached a stalemate. The Federal mediators see their role as lending credibility and assistance to the pros as they work with their respective committees to "close" the deal. The dose of reality the Federal mediators say they inject in a caucus is often no more than reiterating what the pro has been saying all along. The only difference is that when the mediator says it, it's from a "neutral mouth." By adopting the role of orchestrator, the mediator provides the forum for the committees, guided by their pros, to directly negotiate their agreement. ☐

FOOTNOTES

[1] On the properties of common-sense theorizing, see Harold Garfinkel, *Studies in Ethnomethodology* (New Jersey, Prentice Hall, 1967), and Aaron Cicourel, *Cognitive Sociology* (New York, The Free Press, 1974).

[2] As a participant observer, intermittently over a 3-year period, I attended 16 mediation cases with nine different mediators from both a State office of conciliation and arbitration and a field office of the Federal Mediation and Conciliation Service.

The process of selecting cases to attend was different for each service. State mediators allowed me virtually open access to any case. They would open their appointment books, tell me what was coming up, and I would pick a convenient date and case of interest. Federal mediators did roughly the same thing, but made it clear that certain cases would be off limits. These were the well publicized, "big" cases and those where the relationship between the parties was such that an outsider might exacerbate what was already a volatile situation. The State cases I observed thus represent a fair sampling of a typical caseload. Observed Federal cases also represent a typical caseload, except for the 1 percent described as "problematic" or "headline getters."

[3] Inexperienced and diffuse committees, particularly those on the management side, have been identified as a distinguishing characteristic of public sector bargaining. See Thomas Kochan, "A Theory of Multilateral Bargaining in City Governments," *Industrial and Labor Relations Review*, July 1975, p. 526; and Kenneth McLennan and Michael Moskow, "Multilateral Bargaining in the Public Sector," *Proceedings of the 21st Annual Meeting*, Industrial Relations Research Association (Madison, Wisc., IRRA, 1968), pp. 34–41.

A note on communications

The *Monthly Labor Review* welcomes communications that supplement, challenge, or expand on research published in its pages. To be considered for publication, communications should be factual and analytical, not polemical in tone. Communications should be addressed to the Editor-in-Chief, *Monthly Labor Review*, Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

Labor-management panels: three case studies

JAMES W. DRISCOLL

Cooperative departures from traditional collective bargaining behavior have begun to interest scholars and practitioners.[1] Former Secretary of Labor John Dunlop has chaired the meetings of an informal Labor-Management Group at the national level to make recommendations on macroeconomic policy. Numerous local communities now support area-wide labor-management committees. And numerous cooperative programs have appeared in local plants, including quality-of-worklife programs at General Motors and in-plant committees in the steel industry, under the auspices of the Federal Mediation and Conciliation Service, and in the Scanlon Plan.

Despite the recent chill in U.S. union-management relations, cooperative programs have arisen because the two adversaries increasingly face common problems.[2] Challenges to both parties are presented by demographic and attitudinal shifts in the work force, new governmental regulation, technological change, and foreign competition.

All new programs in collective bargaining aiming to answer these challenges share a common behavioral denominator: they encourage joint problem-solving rather than traditional bargaining. Richard Walton and Robert B. McKersie popularized the distinction between these two techniques of conflict resolution.[3] Bargaining conceals information in order to extract concessions from an opponent; problem-solving relies on sharing information in open discussions. Rather than the exchange of proposals, problem-solving includes careful identification of joint concerns, generation of a range of possible alternatives, and the selection of an alternative to maximize joint benefits.

Research on these recent problem-solving efforts has largely consisted of broad overviews and testimonials by their proponents. Our own recent study takes a look at three cooperative innovations, running the gamut from success to failure. Our purpose was to learn whether cooperative problem-solving between adversaries in collective bargaining works, and what factors facilitate its success.

Study of cooperative efforts

Case I describes an attempt to improve the negotiation of contracts through an industry committee. Case II focuses on efforts to improve the administration of the grievance procedure in one plant of a large company. Case III deals with issues outside the scope of traditional collective bargaining in a quality-of-worklife project at a hospital.

In each case, we primarily gathered data by interviewing as many of the regular participants, past and present, as possible. We interviewed 83 participants (about half of those involved), including some third-party participants and about equal numbers of union and management representatives.[4] Joint meetings were also observed in our study.

The retail food committee

Collective bargaining in the retail food industry is extremely decentralized, with contracts signed in individual cities. Unions have been able to play one local employer against another in highly unionized areas of this competitive product market. Along with a skilled work force, this has led to higher wage levels than those of workers in other retail trades.

The industry also has a high profile. Labor and management felt that unless they agreed to address common problems in collective bargaining, the industry would be subject to continued wage-price controls (in early 1974). To reduce this possibility, the three major unions in the industry—the Retail Clerks, the Meatcutters, and the Teamsters—met with the major supermarket chains and employer association representatives in April 1974 to form the Joint Labor-Management Committee of the Retail Food Industry.

Wayne Horvitz, former chairman of the industry's Tripartite Wage Stabilization Committee during the period of controls, was chosen as permanent chairman of the Joint Committee.

James W. Driscoll is an assistant professor at the Sloan School of Management, Massachusetts Institute of Technology, Cambridge, Massachusetts.

Committee members included the presidents of the international unions and the chief executives of the major supermarket chains. A steering committee was also established, consisting of the labor-relations vice presidents of the companies and staff officials from the unions. The steering committee met monthly, while the original top-level executives convened quarterly to set policy.

An early start tackling issues. The committee examined collective bargaining and general industry problems. It published some general principles to guide contract negotiations in the industry.

However, the national recommendations have not become standard practice in local negotiations, although the committee has targeted key negotiations for national attention. It has convened local conferences to help identify problems before contract negotiations begin, thereby reducing the possibility of work stoppages.

In addition to institutionalizing pre-negotiation conferences, the (neutral) chairman and other committee members worked closely with the Federal Mediation and Conciliation Service in mediating a number of deadlocked negotiations, avoiding several unnecessary work stoppages and shortening others.

The steering committee has also initiated action on other problems. In 1976 it undertook a union-management study of personal protective equipment for meatcutters, because both parties were dissatisfied with a regulation proposed by the Occupational Safety and Health Administration (OSHA). As a result, the committee came up with a more workable clarification of the standard providing greater protection to workers and acceptable to OSHA.

More recently, the committee has sponsored studies of potential industry health hazards growing out of concerns about "meatcutters asthma" and the use of polyvinyl chloride wrapping paper, and of the cost of health benefits under collectively bargained benefit plans. The health proposals could help reduce benefit costs, while maintaining or increasing benefit levels for workers.

The committee's specific accomplishments stem in large part from the effort of its permanent third parties and especially the original chairman. He held it together in its early days and mediated some key contract disputes. Later, when the steering committee became bogged down (in part from antagonisms generated during contract negotiations) the chairman reactivated the executive committee to provide policy direction from a group that was not engaged in continuous negotiations.

Mixed reviews. In summary, the steering committee has taken action on a number of fundamental industry problems. For this reason, most of the labor members praised the committee. Company representatives were dissatisfied, however, because they wanted the committee to help reduce the upward pressure on wages from collective bargaining. However, the companies also applauded the committee's work, when specific accomplishments were considered.

The disappointment of company members does highlight a major shortcoming. Although it is involved in settling local disputes, the committee has not enabled the parties to achieve a structural breakthrough in market-area bargaining. Negotiating contracts for larger geographical areas facing similar market conditions might allow greater stability and lower pressure on wages than current fragmented bargaining patterns. As a consequence, the frequency of local disputes might decline. Despite progress in some local areas and the merger of two participating unions—the Clerks and the Meatcutters, the structural problems of collective bargaining in the industry remain.

A small plant's alternative

Pressure from external events forced union and management representatives in a local plant of a large multinational manufacturer to consider an alternative to traditional collective bargaining. Shortly after the founding of this small plant in 1969, demand for its product slackened. As a local policy, workers were not laid off, but were used as janitors. Union-management antagonisms developed, which finally led the corporate industrial relations staff to recommend that no new work be assigned to the plant.

By 1972, the plant's employment had dropped to 35 in the bargaining unit. A consultant from the corporate organizational development staff, which is separate from the industrial relations staff, began to work with the plant management to improve its effectiveness. The consultant quickly became aware of the labor-management hostility and offered his help, which was accepted by the plant manager.

From early-1973 to mid-1974, the consultant initiated, designed, and implemented a series of multiple-day meetings at which union and management representatives discussed their differences in a carefully orchestrated format. All local union officers and members of the bargaining committee met first with the plant manager and his staff and later with the production supervisors in the plant.

In the initial meetings, each group openly vented its dissatisfaction with the other side. Most members participated in the discussion, and both sides acknowledged some of their own problems. They subsequently agreed on areas where joint action was needed by top leadership.

Relations improve. These meetings dramatically improved the collective bargaining climate, as both sides unanimously reported. Relations among the participants of the meetings improved immediately, and most said that they could now trust opposing members to tell the truth more often.

More importantly, the plant personnel manager and the local union president agreed on two supplements to the contract: one to revise the assignment of overtime, the other to specify job ladders within the plant. Both issues had previously caused many grievance problems; now grievances decreased immediately.

The two men also began to meet regularly for open-ended discussions of plant problems. Indeed, when a department that housed new products developed serious labor problems, the two held a 3-day meeting with department representatives.

Finally, the monthly union-management meeting was expanded from a management briefing to include both safety issues and specific concerns raised by the union. In this improved atmosphere, the plant manager was able to support the introduction of new products.

It is always difficult to untangle the effects of such development programs from simultaneous external influences. In this case, new products were brought on line after the first meeting, so employment had returned to 200 following the last meeting. A new personnel manager also came to the plant just before the first meeting; he was the first to hold that position on a full-time basis. Finally, a new union president was elected after the second meeting. He had participated in and had been impressed by the meetings and continued to work closely with management, dominating the local union for several years. Each of these factors undoubtedly helped resolve some of the problems.

Health care union approached

The quality-of-worklife project at the hospital did not arise from external pressures, as in the cases previously discussed. Rather, in 1975, a small independent agency that had been founded to stimulate joint quality-of-worklife projects approached a major union in the health care field. The union suggested the 1,200-bed private, teaching hospital in a major northeastern city as a site for the project. Relevant parties involved with the hospital agreed to support a proposal by the quality-of-worklife agency for Federal funding. The purpose of the externally funded project was to improve patient care and the quality of worklife in the hospital.

During the initial discussion of the project, the union was represented by a vice president; the residents' committee (which then had a collective bargaining agreement with the hospital) sent its leader for the metropolitan area; and the State nurses association was represented by its statewide director of collective bargaining. The hospital was represented by its director, the director of nursing, and the vice president for labor relations. It was the first and only time that top leaders from the various parties met during the project.

A steering committee consisting of representatives of these top leaders was formed to identify a demonstration unit within the hospital, and to establish a control group so the effect of the project could be determined. The steering committee then hired a consulting team, as called for by the proposal, to initiate the project.

Change in consulting team. Following a slow start, the first consulting team was dismissed and a second team was hired, 16 months after the first, top leadership meeting. The latter consultants initially worked with rank-and-file workers on the target ward to identify problem areas for improvement. Later, the consultants extended their efforts to include higher-level supervisors and a major department that provides diagnostic services for the entire hospital.

At the time of the interviews for this report (Fall 1977), the consultant had been working in the hospital for 15 months and had undertaken a number of programs. Workers on the target ward, aided by the consultants, prepared an orientation program for new residents to ensure continuity in day-to-day work practices, a major problem in teaching hospitals. The consultants conducted training sessions on interpersonal skills for workers on the ward, and they began a survey of attitudes and perceptions of performance for the diagnostic department.

It is difficult to assess the impact of these programs on patient care and worklife because the interviews for this report focused only on members of the steering committee. A major evaluation effort is underway to measure both the delivery of service and the attitude of workers. Nonetheless, labor and management representatives felt that the stated goals had not been achieved, and that there had been little impact on the larger collective bargaining system, where most had also hoped to see some improvement.

Two dynamics are worthy of note in understanding the quality-of-worklife project. First, the director of the hospital who endorsed the project was replaced shortly afterward by a successor whose mandate was to cut costs. Second, the consulting team worked primarily with employees in the target ward, members of the diagnostic department that was being surveyed, and with a few steering committee members. The consultants did not develop the steering committee to be a problem-solving group.

Guidelines offered

Cooperative projects emerged from these cases not as panaceas, nor as surefire successes. Rather, practitioners must exercise caution in the face of optimistic claims for joint programs and care in their execution. Based on the three cases studied, it is possible to offer the following guidelines for cooperation:

- Do not expect certain success.
- Examine the initial situation to predict the success of the program; specifically, the felt need for change, the mutual legitimacy of the parties, and support from top-level management.
- Expect more interpersonal changes and indirect effects than specific accomplishments.
- Attempt problem-solving at any hierarchical level.
- Engage a third party with labor-relations experience and behavioral-science skills.
- Despite the increased risk of failure, identify common objectives early.
- Involve "line" officials of both union and management.
- Develop a cohesive group of labor and management representatives.
- Avoid challenges to union or management authority.
- Attempt change in an entire, largely self-contained social system.

The three cases not only identify a probable pattern of factors facilitating cooperative problem-solving, but also suggest a tentative strategy to implement such a change. These guidelines stress the need for participants in a joint effort to monitor the *process* of the change effort as well as specific substantive issues. □

Foreign Labor Developments

Employment training in France: firm and worker experience

Dorothy G. Sparrow

Have French workers benefited from the 1971 law which required firms to provide education and training programs for workers? A series of interviews with a group of 50 workers and managers in 10 firms revealed that worker participation in training programs had increased by 69 percent since the law was enacted. Also, workers reported improved job satisfaction which they attributed to the availability of the programs and said that chances of promotion for lower level employees were improved.

To aid in meeting the dual challenge of rapidly changing occupational requirements and the growing demand for broader economic and social opportunities, the French National Assembly in July 1971 passed the law for Continuous Training *(Formation Professionnelle Continue)*. The three key provisions are:[1]

1. Employers with 10 employees or more are obligated to pay a payroll tax, currently 1 percent, into a National Training Fund. With establishment of training for their workers, employers are reimbursed.
2. Every worker has a right to a paid training leave.
3. Governmental agencies coordinate policies and participate at all levels to facilitate and ensure application.

This report examines the experience of firms and workers since the passing of the law, focusing on the following questions:

1. Has the training facilitated labor force adaptation to economic and technological change?
2. Do workers obtain significant benefits in terms of improved access to training, improved promotional opportunities and salaries? Do the least-skilled workers share in these benefits?
3. Has imposition of a payroll tax on all employers increased training opportunities?

The study is based on a series of interviews with a group of 50 workers and managers in 10 firms in banking, electronics, food distribution, metallurgy, pharmaceuticals, textiles, transportation, and a public utility.

Continuous Training was the capstone of a decade of developing employment training policies. Industrialization of a predominantly agricultural society and rapid growth following the close of World War II increased the demand for skilled workers and created new occupational requirements. A significant aspect of the origin of *Formation Continue* is that its enactment represented legislative ratification of prior agreements negotiated by industry and labor representatives. The accord set forth joint responsibilities for developing and participating in vocational training programs:[2]

- to permit each worker to increase his knowledge and skills in relation to his own aspirations and perspectives on employment;
- to give firms the incentive to develop training policies compatible with their needs and potentials; and
- to give labor organizations the possibility of contributing to the development and functioning of training institutions which fill individual and collective needs.

One of the primary purposes of *Formation Continue* was to make the highly structured, traditional educational system more flexible and more responsive to current demands. The consensus which supported *Formation Continue* was based on the perception that the traditional educational and training system was inadequate and that benefits of a better trained labor force for employers may also increase promotional opportunities.

In France, employment status in terms of skill level and compensation is directly related to the level of educational certification. A Certificate of Vocational Education, obtained after 1 year of study, permits access to unskilled jobs. Entry in skilled trades is secured through completion of a 3-year program which leads to the *Certificat d'Aptitude Professionnelle* (CAP) for each skilled occupation. A *Brevet Professionnel* (BP) is obtained with an additional 2 years of technical training.

Employers view much technical training as inadequate, irrelevant, and often producing graduates lacking even basic skills. The system of "conventions"—permitting employers to contract with public and private institutions—was to stimulate competition with the existing system. For many workers, the educational establishment was viewed as an entrenched elitist bureaucracy

which had succeeded in limiting educational opportunities to the privileged few.

The role of employers

Employers, both in firms and in employer associations, play a leading role. Employers may fulfill their obligation in one or more of the following ways: they may organize training in the firm; finance training by contracting with an outside institution; contribute to a joint employer-union training fund; make payment to an approved training institution; or make payment to the Treasury.[3]

Within the firm, training policy is formulated by top-level management. Administrative responsibility in large firms rests with the training director, and in smaller firms with the personnel director. The training director is responsible for assuring training facilities and personnel either in the firms or in public or private institutions. He or she acts as mediator between top management and workers' representatives in development of training plans in plants with active Works Councils. Management draws up a training plan and budget which are submitted to Training Committees at the central office level and to Works Councils *(Comités d'Entreprise)* in plants and branch offices for comments from worker representatives. The training plan incorporates not only firm projection of manpower requirements over a 3- to 5-year period, but also individual requests for training.

Employer associations in leading industries have established new training centers. Efforts are made to obtain the participation of representatives of educational institutions, the employment service, vocational training centers, and unions. The role of the employer associations varies from region to region. In the North, they act as a clearinghouse of information on educational and training programs and promote the exchange of ideas and experiences. In an agricultural region undergoing rapid industrialization, the association established a training center offering more than 200 courses in many occupations at all levels.[4] Courses are also offered to the unemployed, particularly the young and women entering the labor market.

Role of the unions

Although generally supportive of *Formation Continue*, leading labor organizations expressed concern with the application of the law. One union argued for recognition of courses by diploma, in view of the significance of certification for skilled employment status. Other unions were greatly concerned that firms might provide merely narrow, specialized training, of benefit only to the firm, and pressed for general educational opportunities. Labor also remained on guard against misuse of the law leading to reduction in the time and scope of preemployment education, so recently enlarged.[5]

Among the firms in the study, the role of union representatives varied. In all firms, worker representatives obtained health and safety courses for the employee, urged extended opportunities for the least-skilled workers, women, immigrants, and those workers over age 45. In general, union representatives seek more promotional training as opposed to narrow, technical courses which tend to be firm-specific. However, in the accords on employment security and vocational training it was the Works Council and not the Union Section which was given a consultative role.[6]

Although all firms above a given size have been required to establish a Works Council since 1945, not all firms have complied. In some instances the role of the Works Council is limited, often confined to considering employee social benefits. The purpose of a July 1976 amendment to *Formation Continue* was to strengthen the consultative role of Works Councils. Protesting the lack of a right of appeal in case of disagreement with the Works Council, two unions would not sign the agreement preceding the 1976 amendment. One of the unions was a strong proponent for broadening individual rights to a training leave,[7] increasing worker participation in policymaking, and seeking greater responsiveness of public education authorities to locally expressed needs.[8] The active role of union representatives on Works Councils has supported increased opportunities for less advantaged workers.

Types of training offered

Formation Continue serves firms undergoing both expansion and contraction in employment. In firms with employment growth, increases in training facilitated adaptation of new employees and in firms with stable or declining employment, retraining for current employees. Retraining provided replacements for retiring supervisors, updated the skills of older employees, and developed new skills for new job positions.

Differing sharply in employment trends and in occupational composition, the transport and textile firms covered in this study demonstrate the significance of *Formation Continue* for labor force adjustments. In the transport firm, one-fifth are professional workers and more than one-half are skilled workers. In the textile firm, three-fourths of the work force are unskilled. Training of professionals in transport may require 700 hours per course, compared with 144-hour courses for skilled textile workers.

Data for the transport firm show shifts in training emphasis from long promotional courses to short technical training and increased employee participation from 1975 to 1976. (See table 1.) However, in 1976, hours per person for technicians, assistants, workers, and employees decreased, while hours for engineers, managers,

Table 1. Employee participation in training in a transport firm, by type of training, 1975–76

Type of training	Trainees		Hours of training		Distribution of hours		Hours per trainee	
	1975	1976	1975	1976	1975	1976	1975	1976
All training	251	529	16,088	18,875	100	100	64	36
General education	112	93	2,638	1,923	17	10	23	21
Relations in the firm	22	100	593	6,670	4	35	26	67
Technical training	98	324	3,329	8,862	20	47	33	27
Promotional training	19	12	9,528	1,420	59	8	501	118

and supervisors increased. (See table 2.)

Prior to *Formation Continue*, training in the textile firm was limited to on-the-job training. Job rotation occasionally led to promotion to plant director. In the textile firm, *Formation Continue* improves and maintains worker skill competence, facilitates adaptation to technological and technical changes in production, and provides promotional opportunities to younger workers. In all firms, personnel directors made clear there is no direct connection between training and promotions. However, in the textile firm, the director noted that the distinction is arbitrary because technical training not infrequently is followed by promotion.[9]

Training in the supermarket firm includes short, specialized courses for employees and somewhat longer technical training for supervisors and store managers. Short courses train personnel in every department: cheese-cutting, fresh produce, meats, and seafood. Subjects include "notions of quality in fresh fruits and vegetables," "display," and "specialty preparation," reflecting recognition of traditional values in modern methods of food distribution. Although training tends to be limited to the specialized courses, participating employees have benefited from the firm's internal promotion policies. Promotions occur from entry level to managerial positions. In 1975, 16 percent of management personnel were internally promoted.[10]

Within the firms, the extent of promotional training varies, not only with the proportion of professional and skilled personnel, but also with the training policy of the firm. The long 2- and 3-year courses leading to the CAP and BP degrees are most frequently observed in banking and in the public utility. Operating in the nationalized sector with a tradition of employment security, these firms have elaborate employee career development policies. In both industries, promotional training has been important in areas of technological and technical advance.

Technology changes occupational requirements. A major purpose in training was to adapt the work force to the impacts of both technological and technical change on occupational requirements. Technological change occurred, not only in the application of advanced knowledge to production processes, but also in what Edwin Mansfield has defined as:[11]

> . . . new methods of producing existing products, new designs which enable the production of products with important new characteristics and new techniques of organization and management.

In a country until only recently dominated by its agricultural sector and single proprietor shops, the growth of modern forms of mass distribution and financial services falls within the broader definition of technological change. Between 1963 and 1972, employment in agriculture declined from 19.5 to 12.9 percent of total employment, industrial employment remained stable at 40.3 percent, transport increased 5.8 to 6.1 percent, and the service sector increased dramatically from 30.3 to 40.7 percent.[12] The service sector created new occupations at all levels, from office and sales employees to professional administrators, managers, and technical experts. In industry, technical changes in equipment and materials, as well as technological change, affected skill requirements.

The role of mass distribution has increased significantly,[13] accompanied by "a profound change in the economic structure of the commercial apparatus, the objectives, the forms of organization and techniques utilized by the firms."[14] In a society accustomed to shopping daily for fresh produce, the introduction of frozen foods is a major technological change. Personnel must be trained in new methods of food preservation to guard against losses. Creation of numerous managerial positions in supermarkets required training for a full range of administrative responsibilities. General education, recommended for employees and supervisors as well, is viewed as a desirable and necessary complement to the specialized programs.

Technological and technical change affected occupational requirements in the metallurgical plant and the textile firm. Many phases of production are electronically controlled and monitored by computers, creating positions for computer programmers. Installation of automated equipment required retraining for electricians and related occupations in industrial design and electronics. Changes in materials brought technical

Table 2. Employee participation in training in a transport firm, by occupational level, 1975–76

Occupational level	Trainees		Hours of training		Distribution of hours		Hours per trainee	
	1975	1976	1975	1976	1975	1976	1975	1976
All occupations	251	529	16,088	18,875	100	100	64	36
Engineers and managers	29	29	800	935	5	5	27	32
Supervisors	31	67	805	3,458	5	18	25	52
Technicians and assistants	78	145	4,183	5,506	26	29	53	38
All other employees	113	288	10,300	8,976	64	48	91	31

change: stainless steel in metallurgy and synthetic materials in textiles.

Reorganization and increased firm size have increased administrative responsibility, requiring technical training for managers, particularly in personnel. In the metallurgical plant, automation and technical change have increased productivity substantially. In metallurgy, most training has served to update the skills of older workers. A few workers have been retrained to fill new positions, such as computer programmer. In the textile firm the purpose of technical training is to develop versatile workers with all-around skills.

Worker experience

Characteristics of worker group. The worker group interviewed in 1976 and again in 1977, was diverse with respect to age, sex, industrial sector, and occupational level. About one-half were production workers, the remaining were employees in service sector industries. Thirty-three were under 35 years of age, and the same number were male. Those interviewed tended to have attained educational levels higher than that of their parents. Whereas 11 had parents who had received no diploma, only 4 workers had not obtained any diploma. Ten workers had received the Baccalaureat, the French prerequisite for university admission, compared with only 4 of the parents. Production workers were interviewed in metallurgical, textile, and pharmaceutical plants; service sector workers were in banking and supermarket firms.

Worker responses. Workers responded to a questionnaire to give their reasons for taking courses and to evaluate the results. One-third responded that their goal was improved professional qualifications. Although some had a particular position in mind, most viewed the course taken as a step toward future improved occupational opportunities. Ten percent sought to improve current skills; another 10 percent wanted to improve their general background. Seven specified "a better job;" four expressed interest in new jobs in the firm. Less than half stated that they took the course at the suggestion of supervisors. However, only eight indicated they had requested the course on their own initiative. Individual requests were most common in banking where the CAP is required for all new employees, and additional requests are made to complete the program in the second year.

Other workers referred to "improved ability to understand the effects of technological changes in process or equipment on their work," and "improved sense of relationship, both in terms of human relations and firm operations as a whole."

A few workers were less than enthusiastic. Two older textile workers claimed technical training added little to their background. A supervisor expressed preference for the greater thoroughness of apprenticeship training. Workers interested in training unrelated to their jobs or the firm resented informational courses. In general, however, workers expressed improved job satisfaction. A newly promoted bank employee said, "I feel more at ease in my new position." Greatest satisfaction occurred where promotion followed. Worker interest in general education had two objectives, personal and cultural environment and improved vocational background. Women were more likely than men to express these interests. However, scheduling of most general education after work, often in locations remote from worker residences, restricts participation.

Improvements in occupational status. Despite the fact that management emphasized that there is no automatic connection between training and promotion, most workers undertook *Formation Continue* in the hopes of improved job opportunities. Consequently, younger workers and skilled and professional workers tended to have greater rates of participation.

For 32 percent of the group (16 workers), *Formation Continue* was followed by promotion. Promotion involved jobs with more responsibility, increases in salary, and in the case of four production workers, improved professional rank. Of the 17 women, 4 were promoted, compared with 12 of the 33 men. Among production workers, promotions occurred in stable and declining industries to replace retiring personnel. Promotions may well be related to educational attainment: 7 of the 16 workers had primary diplomas, the remaining, the CAP or the Baccalaureat. The predominance of promotion among more educated employees is not surprising. Employers are traditionally more interested in educating employees with prior training, because of higher payoff probabilities in increased productivity. Educated workers tend to have more of a "taste for education" and are more likely to seek it out. It is important to note, however, that promotions were not confined to the more educated workers. *Formation Continue* has created possibilities formerly limited to upper level employees in a few firms.

Between 1972 and 1977, national trends in worker participation in firms' training show a 69-percent increase, from 1,050,000 to 1,774,000 workers.[15] Average length of program diminished from 74 to 57 hours per trainee.[16] In 1977, the number of courses exceeded the number of trainees by 293,000, supporting the evidence noted in all firms that many participants have taken more than one course.

By occupational level, there has been a slight decrease in participation in training opportunities by professionals and managers, the supervisory group, and to a lesser extent, by unskilled workers during the 1972–77 period.

In 1977, participation by occupational level was as follows: unskilled, 15.8 percent; skilled, 45.7; supervisors, 23.6; and engineers and managers, 14.9 percent.[17] Skilled workers and employees with a high school diploma or equivalent increased their participation almost 10 percent since 1972. The preponderance of skilled worker and employee participants is directly related to the high proportion of technical training programs.

Extent of training opportunities. Changes in the extent of training opportunities with the inception of *Formation Continue* may be measured in terms of firm participation, the role of employer associations, and worker participation. From 1972 to 1974–75, the numbers of participating firms and trainees increased. Since 1974, there has been a slight decline. (See table 3.)

Small and medium-size employers, many for the first time, are training employees in public or employer-established training centers. Since 1972, smaller firms have increased participation in terms of percent of payroll expended, but have not yet reached the 1 percent level, due in part to the greater difficulty of scheduling training leaves and to fewer promotional opportunities.

Examining changes in training categories assists in evaluating training opportunities. National data show slight shifts in emphasis. Technical training remains most significant, increasing from 72 to 75 percent of the total from 1972 to 1977. The role of long, promotional programs show little change, varying only from 12 to 11 percent. Retraining to prevent unemployment increased from 1 to 3 percent.[18]

Another measure of training opportunities is the extent of individual training leave requests. Although in some firms directors had noted a slight increase, as borne out by worker interviews, national data indicate requests diminished to 3 percent of the total number of trainees in 1977.[19] The decline is attributed to the stringency of legal requirements, such as the maximum number of employees permitted simultaneous leave in an enterprise. Because worker motivation is, in part, due to perceptions of promotion opportunities, the decline in employment, particularly in some industries, may be a factor.

The effect of the payroll tax

An important aspect of *Formation Continue* is the universality of the payroll tax. All employers share some burden and incentive in the creation of training facilities. Underinvestment in training by firms occurs where the training decision rests solely with the individual firm. Employers are aware that the workers they train may well seek opportunities elsewhere. As one personnel director commented:[20]

> "Yes, it is true we do occasionally lose workers we have trained. However, we do not view that as a loss. First, the very next day it is quite probable that a similarly trained worker from another firm may walk in the door. And, secondly, we believe that the general increase in productivity resulting from *Formation Continue* benefits all firms, and therefore society as a whole."

Table 3. Number of participating firms and trainees, selected years, 1972–77

[Number in thousands]

Year	Number of firms	Number employed	Trainees	
			Number	As a percent of total employed
1972	113	9,760	1,050	10.7
1974	121	10,470	1,790	17.1
1975	123	10,440	1,840	17.6
1977	121	10,079	1,774	17.6

SOURCE: *Projet de Loi de Finances pour 1979,* Formation Professionnelle et Promotion Sociale, p. 40.

Employer support of *Formation Continue* derives, not only from increased ability to shape training to suit firm requirements, but to profit from the general increase in skills of a larger trained labor force.

Robert Gordon has pointed out that wages tend to rise particularly rapidly, as well as prices, in sectors experiencing labor shortages, and tend to spill over into sectors in which unemployment exceeds vacancies.[21] By maintaining training facilities throughout cyclical changes, a payroll training tax system, together with other manpower policies, may assist in reducing inflationary pressures.

Formation Continue helps compensate for employee underinvestment in training.[22] Workers taking courses during work receive their normal salary. The long promotional courses are taken, in part, during work time.

THE APPLICATION OF *Formation Continue* in connection with firm redesign of jobs, and with the application of technological changes in production, suggests a fruitful area for future research. There is a complex interaction between work reorganization, technological change, job content and training. The role of unions in assuring worker benefits with the application of training in work reorganization will be important to observe. Study of the operation of *Formation Continue* indicates that active worker representation in development of training plans is essential to guarantee benefits to the least advantaged workers under a system in which employers play the leading role. ☐

Cost-of-living indexes for Americans living abroad

The U.S. Department of State has prepared new indexes of living costs abroad for Americans in Buenos Aires and London. The new index for Buenos Aires is 7 percent higher than the previous index and for London 6 percent higher. (See table 1.) The periods between survey dates are 3 months for Buenos Aires and 6 months for London.

For Americans in Buenos Aires, average prices of goods and services were up 20 percent more than in Washington, D.C., between survey dates, but the peso depreciated 11 percent against the dollar and offset most of the relative price rise. The new index for London reflects primarily the British rise in living costs, including the July 1979 value-added tax increase; the British pound appreciated slightly relative to the U.S. dollar over the 6 months.

Because exchange rates are subject to sudden shifts, it is advisable to check the prevailing rates whenever using the indexes of living costs abroad. The indexes for these and all other reporting cities are published in quarterly reports entitled *U.S. Department of State Indexes of Living Costs Abroad and Quarters Allowances*, available on request from the Office of Publications, Bureau of Labor Statistics.

Table 1. Indexes of living costs abroad, excluding housing and education, February 1980

[Washington, D.C. = 100]

Country and city	Survey date	Monetary unit	Rate of exchange per US $1	Local index
Argentina: Buenos Aires	Oct. 1979	Peso	1483	142
Australia: Canberra	Apr. 1979	Dollar	0.8751	121
Belgium: Brussels	Mar. 1979	Franc	30.0	158
Brazil: Sao Paulo	Apr. 1979	Cruzeiro	23.0	115
Canada: Ottawa	Dec. 1978	Dollar	1.17	99
France: Paris	Mar. 1979	Franc	4.32	166
Germany: Frankfurt	Mar. 1979	Mark	1.87	164
Hong Kong: Hong Kong	May 1979	Dollar	5.08	112
India: New Delhi	July 1979	Rupee	8.11	93
Italy: Rome	Oct. 1978	Lira	840	114
Japan: Tokyo	Mar. 1979	Yen	212	183
Mexico: Mexico, D.F.	Feb. 1977	Peso	22.0	78
Netherlands: The Hague	Feb. 1979	Guilder	2.06	154
Philippines: Manila	Jan. 1979	Peso	7.38	89
South Africa: Johannesburg	Dec. 1977	Rand	0.8697	91
Spain: Madrid	Dec. 1978	Peseta	69.0	120

Significant Decisions In Labor Cases

Substance of seniority

In its 1977 *Teamsters* decision,[1] the Supreme Court approved a two-track seniority system for overland and city truck drivers. A move from one classification to the other left the worker at the bottom of the unit's seniority ladder. The Court ruled that such a plan was immune from the antidiscrimination provisions of Title VII of the 1964 Civil Rights Act, even though it may lock in the effects of pre-act discrimination. Thus, *Teamsters* identified the congressional intent not to disturb existing "bona fide" seniority systems, while it instantly created a slew of questions about the legitimate content of such plans.

Acknowledging the need for some judicial guidance, the Supreme Court took the opportunity recently presented by *California Brewers Assn.*[2] to set broad guidelines defining the characteristics of seniority systems, based on their nature and purpose. As a result, the Court ruled that entry to a preferred-benefit track can be limited to those who have held their jobs for at least 45 weeks in a calendar year. Such a rule operates on the commonly accepted basis of seniority—employment longevity—the Court reasoned, even if it may not always operate consistently with an employee's cumulative length of service.

Building on *Webster's* definition of "seniority," Justice Potter Stewart's majority opinion concluded that the seniority systems Congress meant to exempt from the normal operation of Title VII also could include rules not based on the time spent in employment:

> . . . In order for any seniority system to operate at all, it has to contain ancillary rules that accomplish certain necessary functions, but which may not themselves be directly related to length of employment. For instance, every seniority system must include rules that delineate how and when the seniority time clock begins ticking, as well as rules that specify how and when a particular person's seniority may be forfeited . . . rules that define which passages of time will "count" towards the accrual of seniority . . . [and] rules that particularize the types of employment conditions . . . governed by seniority . . .

The multi-employer collective bargaining agreement covering workers in most California breweries establishes several classes of employees, each with specific rights as to hiring and layoffs. "Temporary" employees are those who have worked at least 60 days in the preceding calendar year. "Permanent" employees, those who have completed 45 weeks of employment in one classification during a calendar year, are laid off last (in reverse order of group seniority) and maintain priority status in rehiring for up to 2 years.

Black workers alleged that the 45-week rule for achieving permanent status was actually a classification device resulting in a discriminatory impact on black workers, in violation of Title VII. The fact that a black worker had never achieved permanent-employee status was submitted as evidence of the disparate impact. Because it found the 45-week rule to be an arbitrary classification device, the Ninth Circuit Court of Appeals ruled that such rules could not be part of a seniority system exempted from Title VII.

In overruling the appeals court, the Supreme Court not only outlined the scope of possible provisions in seniority systems, but it stressed the freedom of parties to collective bargaining agreements to shape such provisions. However, Stewart also issued a mild warning that only rules comforming to "commonly accepted notions concerning the acceptable contours of a seniority system" would be permitted. As some general guidelines, he indicated that an educational standard, an aptitude or physical test, "or a standard that gives effect to subjectivity" would be impermissible seniority system rules under Title VII.

It is interesting that Stewart referred to last year's *Weber* ruling[3] (permitting voluntary union/employer affirmative action programs) to endorse the Court's emphasis on the freedoms available under collective bargaining. Although such a position has been a feature of court decisions under the National Labor Relations Act, *Weber's* extension of it to Title VII may continue to provide additional influences other than on affirmative action programs.

Even though the Court has sanctioned a broad array of negotiated seniority system rules, aggrieved workers will still remain free to show that such rules were not established in good faith (and, therefore, not entitled to the exemption for "bona fide" plans under Title VII) or that the *operation* of such rules has produced differences

---

"Significant Decisions in Labor Cases" is written by Gregory J. Mounts of the *Monthly Labor Review* staff.

in employment conditions resulting from an intention to discriminate. Thus, California's black brewery workers will have an opportunity to show any discriminatory aspects of the 45-week rule or other seniority system rules on remand in district court.

Deflating damage awards

The Supreme Court recently entered into the inflation-fighting business by seeking to limit high damage awards by juries under the Federal Employer's Liability Act. The Court sided with a vanguard of lower courts by ruling that employers could calculate and present to the jury the *after-tax* future earnings of a victim. Until now, standard practice was to assume that the prediction of a deceased or injured wage earner's tax burden was too speculative and complex for jury deliberations. Writing for the Court, however, Justice John Paul Stevens reasoned that all the other variables involved in calculating lost future income—continuity of employment and health and the estimation of future expenditures, interest rates, and inflation—are equally complex. He also noted that juries are "increasingly familiar with the complexities of modern life." In addition, the 7-to-2 majority found that it was wrong for a judge to refuse to instruct a jury that any award of damages under the law would not be subject to income tax. Despite the clarity of the law on this point, the Court reasoned that the jurors may inadvertently provide a larger sum by considering the imaginary tax consequences. *(Norfolk and Western Railway Co.*[4])

In the present wrongful-death case, the jury awarded the survivors of a railroad fireman killed in a collision caused by the employer's negligence $775,000. The survivors had only claimed a loss of future gross income of $302,000, while the employer claimed that, on an after-tax basis, the deceased's future earning amounted to $138,327 when discounted to the present. The counsel for the survivors attributed the higher jury award to the pecuniary value of the "guidance, instruction, and training that the decedent would have provided to his children." The employer claimed that the difference resulted from the jurors' mistaken impression that the award was taxable and their use of gross income as the measure of loss instead of after-tax income—the "actual" loss to the dependents of the deceased.

Justice Harry Blackmun, joined by Justice Thurgood Marshall, wrote a vigorous dissent to the majority's concern over the "inadvertent" escalation of such damage awards. He argued that the effect of an income tax is only relevant to the recipient of income. To permit the employer to reduce its payment burden to an after-tax basis creates an important benefit for the defendant in such cases, Blackmun charged. Instead of intending to permit such a windfall for the guilty party, Congress probably intended to provide an additional benefit to the victim of a tort or simply sought to avoid the administrative burden associated with collecting taxes on such awards, he wrote.

Blackmun also dissented from the Court's finding that the jury must be instructed, at the defendant's request, that the damage award is not taxable. Terming it "an admonition to the jury not to misbehave," he reasoned that such instruction could easily lead to a barrage of unnecessary and confusing comments on what and what not to consider.

Paid enforcement

Even though the penalties assessed by the Department of Labor for violations of child labor laws can be used to help defray the cost of enforcing the law, such a practice does not violate constitutional due process requirements, the Supreme Court recently ruled. The Court has ruled in earlier cases that the Constitution prohibits the adjudication of either criminal or civil cases by a decisionmaker who stands to gain based on the outcome of the decision.[5] However, in *Marshall v. Jerrico, Inc.*[6] the Court found that persons charged with enforcing the child labor laws by assessing penalties for violations act more clearly in a prosecutorial manner rather than as final decisionmakers. As a result, the Court reasoned that the relationship between the assessment of fines and their eventual allocation as part of the operating budget is so "remote and insubstantial" that those who assess penalties stand no realistic chance of gaining from the arrangement.

Writing for a unanimous Court, Justice Thurgood Marshall illustrated that an employer assessed a penalty by the Secretary of Labor for a violation of the child labor laws may file for a *de novo* review of such a determination by an administrative law judge within 15 days of receiving notice. The administrative law judge may affirm, in whole or in part, the Secretary's determination or may find that no violation occurred.

In such a review process, those who have assessed a penalty must bear the burden of proof on contested issues; thus, they clearly become the prosecutors, with an impartial third party[7] adjudicating the issue.

Marshall also recognized that, as public officials, prosecutors can be motivated by some of the same improper factors that threaten due process when they affect judicial and quasi-judicial decisionmakers. The Court made clear that it will not apply the same standard for judges as for prosecutors; but Marshall left to another day any determination as to what limits there may be on a financial or personal interest of one who performs a prosecutorial function. He refused to consider such issues in this case because the alleged source of bias is "exceptionally remote." Government workers involved have fixed salaries and could not gain financially; total penalties collected have been a tiny portion of the overall budget; distribution is determined by the national office, not the prosecutors in the field; and such monies are proportioned based on expenses incurred in prosecuting, not on penalties assessed. All of these facts persuaded the Court that such a scheme does not violate the Due Process Clause of the Fifth Amendment to the Constitution.

Legitimacy through living together

Illegitimate children have generally gained access to Federal benefits available to other children if they can demonstrate some relationship with their parents. The Supreme Court has facilitated such benefit equality by striking down dependency restrictions only for illegitimates as unconstitutional—in violation of equal protection guarantees. In a recent case, the Court removed an arbitrary barrier to the distribution of benefits to the illegitimate survivors of Federal Civil Service employees. However, the Court's decision involved a careful interpretation of the underlying statute, without reaching the constitutional issue as had the lower court. A 7-to-2 majority ruled that the requirement that "recognized natural" children "lived with" their parents to be eligible for a survivor's annuity means only that they must have *once* lived in a normal parent-child relationship—not necessarily at the time of the worker's death. (*United States v. Clark.*[8])

Because a solution involving statutory construction is viewed by the Court as preferable to one reaching constitutional dimensions, the majority reviewed the legislative history of the Civil Service Retirement Act to test whether a more liberal interpretation of the "lived with" requirement might interfere with congressional intent.

Writing for the Court, Justice Thurgood Marshall found that earlier versions of the law contained a provision requiring proof of dependency in addition to specifying living arrangements. In 1966, Congress deleted the dependency requirement in order to ensure recovery for the children of female civil servants, who typically earned less than their husbands and accordingly contributed less than the amount (50 percent) required for proof of dependency. Based on the legislative record, Marshall concluded that Congress did not intend to let the "lived with" provision which remained in the law carry the function of the deleted dependency criterion. To view it as such, he wrote, would raise constitutional questions because legitimate and adopted children are not required to show any dependency. Thus, Marshall was able to conclude that the "lived with" provision is satisfied when the recognized natural child has lived with the deceased employee in a regular parent-child relationship, regardless of whether such an arrangement existed at the time of the employee's death. Although not an explicit dependency requirement (which would raise constitutional issues), the "lived with" provision establishes some basis for the economic support intended to flow to the dependent survivors of a Federal worker. ☐

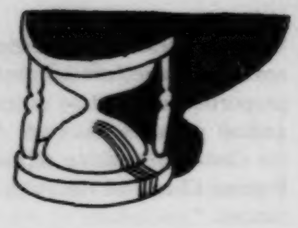
Major Agreements Expiring Next Month



This list of collective bargaining agreements expiring in July is based on contracts on file in the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more.

Employer and location	Industry	Union[1]	Number of workers
ACF Industries, Inc., Carter Carburetor Division (St. Louis, Mo.)	Machinery	Auto Workers (Ind.)	1,500
American Metal Climax, Inc., Climax Molybdenum Co. Division (Climax, Colo.)	Mining	Oil, Chemical and Atomic Workers	2,100
Arizona Steel Field Erectors Association (Phoenix, Arix.)	Construction	Iron Workers	1,300
Armco Steel Corp., 2 Agreements (Pennsylvania & Ohio)	Primary metals	Butler Armco Independent Union; and Armco Employees Independent Federation, Inc. (Ind.)	8,500
Associated General Contractors of St. Louis & 2 others (Missouri)	Construction	Iron Workers	1,600
Associated Guard and Patrol Agencies (Chicago, Ill.)	Services	Service Employees	5,000
Association of Master Painters and Decorators of New York City, Inc. (New York, N.Y.)	Construction	Painters	5,000
Association of Motion Pictures and Television Producers, Inc. (Interstate):			
Technicians Basic Agreement	Amusements	Theatrical Stage Employees	21,000
Television Film Agreement	Amusements	Musicians	2,000
Theatrical Motion Picture Agreement	Amusements	Actors	8,500
Theatrical Motion Picture Agreement	Amusements	Musicians	1,500
Automotive Repair Industry (California)[2]	Services	Machinists	1,000
Bowaters Southern Paper Corp. (Calhoun, Tenn.)	Paper	Paperworkers; and Electrical Workers (IBEW)	1,000
Briggs & Stratton Corp. (Milwaukee, Wis.)	Machinery	Allied Industrial Workers	8,000
Brooklyn Union Gas Co. (New York, N.Y.)	Utilities	Transport Workers	2,300
Columbus & Southern Ohio Electric Co. (Ohio)	Utilities	Electrical Workers (IBEW)	1,350
E. J. Brach & Sons, Inc. (Chicago, Ill.)	Food Products	Teamsters (Ind.)	3,000
Firestone Tire & Rubber Co., Firestone Steel Products Co. Division (Wyandotte, Mich.)	Transportation equipment	Auto Workers (Ind.)	1,050
Floor Covering Association of Southern California, Inc. and 3 others (California)	Construction	Painters	1,600
FMC Corp., Northern Ordnance Division (Fridley, Minn.)	Fabricated metal products	Auto Workers (Ind.)	2,500
Hercules Inc. (Coverington, Va.)	Chemicals	Paperworkers	1,050
Kimberly-Clark Corp. (Memphis, Tenn.)	Paper	Paperworkers	1,100
Leeds & Northrup Co. (North Wales, Pa.)	Instruments	Auto Workers (Ind.)	2,200
Mirro Aluminum Co. (Manitowoc and Two Rivers, Wis.)	Fabricated metal products	Steelworkers	1,800
Non-Registered Drug & General Merchandise Agreement (Portland, Oreg.)[2]	Retail trade	Food and Commercial Workers	2,200
Pan American, Ground Service (Interstate)[3]	Air transportation	Transport Workers	5,850
Restaurant and Tavern Employers (Tacoma, Wash.)[2]	Restaurants	Hotel and Restaurant Employees	2,000
Safeway Stores, Inc. (Interstate)	Retail trade	Teamsters (Ind.)	2,300
Sealed Power Corp. (Muskegon, Mich.)	Machinery	Auto Workers	1,000
Southern Florida Hotel and Motel Association (Miami Beach, Fla.)	Hotels	Hotel and Restaurant Employees	3,000
Teledyne Wah Chang Albany (Oregon)	Primary metals	Steelworkers	1,200
Todd Pacific Shipyards Corp., Los Angeles Division (California)	Transportation equipment	Marine and Shipbuilding Workers	2,500
Weyerhaeuser Co. (Plymouth, N.C.)	Paper	Paperworkers; and Operating Engineers	1,600
White Pine Copper Co. (White Pine, Mich.)	Mining	Steelworkers	1,000
Winery Employers Association (California)	Food products	Distillery Workers	5,000

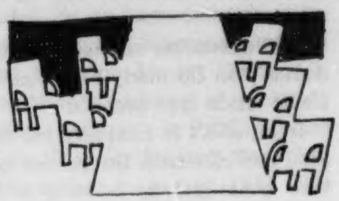
Developments in Industrial Relations



Steel contracts feature pension increases

Operating under the bargaining procedures and deadlines of the Experimental Negotiating Agreement, nine Coordinating Committee Steel Companies and the United Steelworkers union negotiated a new contract. An impasse continuing beyond the April 15 deadline for a settlement would have meant that the unresolved issues would have been submitted to binding arbitration, as required by the negotiating agreement. Discussions were continuing on whether to extend the Experimental Negotiation Agreement to govern the 1983 talks.

The union had stressed that its major concern was winning pension increases for present retirees to help them counter the erosion of their income that had resulted from inflation. In fact, the union waived the May wage escalator adjustment for employees to help the companies meet the cost of the benefit improvements for present retirees. The 33-cent increase would have been the last scheduled quarterly escalator adjustment under the 1977 contract.

The new pension formula for current retirees provides for a two-stage increase, ranging from 70 percent for employees who retired prior to July 31, 1966, to 10 percent for those who retired during July 31, 1977–July 30, 1980. The increases are subject to a $25-a-month minimum and a $250-a-month maximum and, according to the union, will average $182 a month for retirees in the earliest category and $52 for those in the later category. Spouses of deceased retirees also received benefit increases.

There also were several improvements in pensions for employees retiring after July 31, 1980. One was a new minimum formula which provides for a three-step increase in the monthly pension rates. (Employees are eligible for a pension under an alternate percentage formula if it amounts to more than that under the minimum benefit formula.) The August 1, 1982, final-step rates are $17.50 for each of the first 15 years of service, plus $19 for each of the next 15 years, and an additional $20.50 for each year in excess of 30. Under the 1977 contract, the corresponding rates were $13.50, $15, and $16.50.

The settlement provided for a May 1, 1980, wage increase of 25 cents an hour plus a 1-cent increase in the increment between the 33 job grades. The resulting overall range was 25 cents for employees in the lowest grade to 57 cents for those in the highest. The accord also provides for a 20-cent increase on August 1, 1981, 15 cents on August 1, 1982, plus 1-cent increment increases on both dates, bringing the ranges to 20 to 52 cents and 15 to 47 cents. The three increases will be larger for the 85 percent of the employees who are covered by incentive plans, because the increases will be added to their incentive calculation rates, rather than being paid as a flat add-on for each hour worked. In conjunction with this provision, the "earnings opportunity" for iron ore miners was increased to 123 percent of incentive calculation rates, from 115 percent. Shift differentials were increased to 30 cents an hour (formerly 20) for the second shift and to 45 cents (formerly 30) for the third.

In addition to a guaranteed 3-percent wage increase each year, the Experimental Negotiating Agreement guaranteed continuation of the cost-of-living wage escalator clause. As before, employees will receive quarterly adjustments (beginning August 1, 1980) of 1 cent an hour for each 0.3-point movement in the BLS Consumer Price Index (1967=100) for Urban Wage Earners and Clerical Workers. Under the prior contract, adjustments from August 1977 through February 1980 had totaled $1.73. The Experimental Negotiating Agreement also guaranteed a $150 bonus for all employees on the payroll on August 1, 1980, in return for the assurance that there would be no 1980 strike over economic issues.

Improvements in insurance benefits included a $4,500 increase in life coverage, bringing the range to $14,500 to $17,000, and a $500 increase for employees retiring after July 1, 1982, bringing their benefit to $3,500. Sickness and accident benefits, which had ranged from $153 to $211 a week, were increased, in steps, to a $211–$276 range on August 1, 1982. There were a number of changes in health insurance, including a provision for up to 365 days of full coverage in a skilled nursing home (the previous coverage was usually only 80 percent of the cost); a new home health care benefit;

"Developments in Industrial Relations" is prepared by George Ruben and other members of the staff of the Division of Trends in Employee Compensation, Bureau of Labor Statistics, and is largely based on information from secondary sources.

$1,000 maximum annual coverage per person under the dental plan (formerly $750); and increases in the schedule of vision care benefits.

In an effort to minimize the duration and cost of hospital confinements, the parties agreed to a utilization review procedure to be used in conjunction with those hospitals that have such programs.

Other economic provisions included:

- A new $40 safety shoe allowance, payable twice during the contract term.
- A $55-a-week increase in maximum Supplemental Unemployment Benefits for weeks when a laid-off worker is receiving State unemployment compensation and a $65-increase for other weeks, bringing the maximums to $180 and $235.
- An additional week of extended vacation for those employees in the top half of the seniority roster who have 25 years of service and for all employees in the bottom half of the roster (extended vacations are taken every 5 years). Previously, all employees in the top half received 13 weeks (including their regular annual vacation for that year) and those in the lower half received 3 weeks plus their regular vacation for that year.

Recent shutdowns of some operations led to a contract provision requiring the companies to give at least 90 days' notice of planned closings. During the notice period, the parties will discuss the shutdown, after which the company will formally announce its decision to the union.

The employers' demand for the separation of steel fabricating, steel warehousing and other "List 3" operations from steel producing units for bargaining purposes will be analyzed in joint discussions to be concluded by August 1, 1981. The companies had generally contended that competitive reasons required that "List 3" employees be placed on lower pay scales than other employees.

The Council on Wage and Price Stability approved the pay package, saying that it will raise worker compensation by 24.7 percent over 3 years, or 7.65 percent a year, compounded. The council noted that this was "near the bottom end" of the 7.5–9.5 percent guideline for the second year of the anti-inflation program. A council official said the package cost calculations were made by excluding the cost of the pension improvements for the present retirees and assuming that the annual inflation rate will be 7.5 percent.

The nine companies that settled on economic provisions for their 290,000 workers represented by the Steelworkers are United States Steel Corp.; Bethlehem Steel Corp.; Republic Steel Corp.; National Steel Corp.; Jones & Laughlin Steel Corp.; Armco, Inc.; Inland Steel Co.; Wheeling-Pittsburgh Steel Corp.; and Allegheny Ludlum Industries, Inc. Bargaining was continuing on local issues and there was the possibility of strikes at some locations. The Experimental Negotiating Agreement permits strikes over local issues, if they are authorized by the Steelworkers' president.

Bargaining on economic terms was continuing for 160,000 employees of smaller steel companies that generally follow the pattern of the accords negotiated by the nine companies. Based on past developments, the steel contracts are expected to influence coming settlements in the container, aluminum, and copper industries.

Initial contract for steelworkers at Newport News

The Steelworkers' 2-1/2 years organizing campaign at the Newport News Shipbuilding and Drydock Corp. culminated in an initial 43-month contract that provides for general wage increases and improved supplementary benefits.

According to the Steelworkers, the settlement closes one of the "stormiest organizing campaigns in the history of the South." The union said that its new local 8888 at the yard is its second largest in the country and largest in the South. Newport News Shipbuilding is the Nation's largest private shipbuilder.

The first major development in the campaign occurred in January 1978, when the Steelworkers apparently defeated the incumbent Peninsula Shipbuilders Association in a National Labor Relations Board representation election. However, the company filed charges of election "irregularities" with the NLRB and refused to bargain with the union. The Board ruled against Newport News Shipbuilding, but there was a series of appeals within the Federal district courts. In an attempt to force the shipyard to begin bargaining, the Steelworkers struck, beginning in January 1979, but suspended the strike in April of that year. After the Fourth U.S. Circuit Court of Appeals upheld the NLRB's certification of the election results, the company recognized the union as bargaining agent for the 15,500 production, maintenance, technical, and clerical workers and the parties started bargaining.

For production and maintenance workers, the accord provided for a wage increase ranging from 80 cents an hour for helpers and handymen to $1 for specialists and mechanics. Prior to this increase, rates ranged from $3.64 to $8.20 an hour, with most workers earning $4.55 to $7.61. The 235 technical employees received the same initial increase, while the 750 clerical employees received a 10.5-percent increase. Future increases for all employees are 55 cents an hour on August 1, 1981, 50 cents on October 1, 1982, and 10 cents "cost-of-living" increases—not contingent on the movement of a Consumer Price Index—on March 1, 1982, and April

1, 1983. According to the union, more than 90 percent of the employees received or will receive additional pay increases as a result of job upgradings and the adoption of automatic wage progression schedules.

The monthly pension amount for each year of service from July 1, 1969, to December 31, 1977, was increased to $12 for employees retiring on or after April 1, 1980, and to $14 for those retiring on or after October 1, 1982. The previous monthly pension rates were 0.1 percent of average annual earnings for each year of service from July 1, 1969, to December 31, 1974, plus $11 for each year from January 1, 1975, to December 31, 1977. There was no change in the $14 rate for service after December 31, 1977. A new disability pension provision for 15-year employees provides for lifetime benefits, unlike the previous benefit which terminated when the retiree became eligible for social security benefits.

Changes in medical insurance included 180 days coverage of each hospital confinement (formerly 120 days); full coverage of miscellaneous medical services (previously, the hospitalized person was required to pay 20 percent of that portion of the charges in excess of $750); and a $100 a year deductible under major medical coverage (formerly $100 for each family member).

Other benefits included $15,000 of company-financed life insurance for employees (formerly $10,000), and company-financed sickness and accident benefits of $110 to $145 a week, for up to 26 weeks. (Previously, employees contributed toward the cost of the benefits, which ranged from $60 to $95 a week, for up to 13 weeks.)

Despite the settlements, there was a continuing dispute, and the union filed a complaint with the NLRB charging the shipyard with refusing to bargain in good faith with a designers local organized more than 3 years earlier. The company had broken off talks for the unit in the fall of 1979, after a dissident group within Local 8417 petitioned the NLRB for a vote on decertifying the union as bargaining agent for designers.

New York transit employees end strike

An 11-day strike ended in 2-year agreements between 33,000 New York City subway and surface transit employees and the Metropolitan Transit Authority. John E. Lowe, head of the Transport Workers local union, ordered the 31,000 subway workers back to work pending the outcome of their vote on the contract. (Ordinarily, the local's 44-member executive board makes the final decision on a settlement but the board's vote ended in a tie). The matching agreement for the 2,000 surface transit workers represented by the Amalgamated Transit Union was approved by the executive board of the ATU local union.

The agreements provided for an immediate wage increase of 9 percent and an additional 8 percent on April 1, 1981. There also was provision for an October 1, 1981, automatic wage escalator adjustment of 1 cent an hour for each 0.4-percentage point rise in the Consumer Price Index for New York City-Northeastern New Jersey during the 12 months ending in August 1981. The adjustment will be limited to the amount resulting from a 6-percent rise in the index. In addition, 3,400 workers who had been hired since the 1978 settlement and had not received a cost-of-living adjustment provided to other workers, will get an immediate 95-cent "catch-up" adjustment. The Transit Authority also agreed to contribute about $20 million to the unions' health and welfare funds to offset higher costs.

The unions agreed to several of the productivity demands, or "give-backs", that the Transit Authority had sought to minimize labor costs, including a 20-minute-a-day reduction in paid work breaks; the elimination of 2 hours paid time off on election day; combination of certain job classifications; and adoption of a system to eliminate abuse of sick leave. In another cost savings feature, automatic progression from starting to top pay rates was extended for employees on schedules shorter than 2½ years.

New York City Mayor Edward Koch, who did not become involved in the talks, called the settlement an "outrage," saying it would cost the deficit-ridden transit system $271.4 million more over the 2-year period. The Transit Authority, which is under the jurisdiction of the State rather than the city, denied that the cost would be that high, but did not provide a specific figure. Koch insisted that the accord not be viewed as a pattern-setter for the city's upcoming negotiations with various unions to replace agreements scheduled to expire June 30 for 238,000 workers.

Despite the end of the walkout, there were some unresolved matters. The unions were appealing a $1-million fine imposed for violating the State's Taylor Law, which prohibits strikes by public employees. Also, some members of the Transport Workers union were continuing their legal efforts to prevent the vote by the rank-and-file and have a revote by the executive board.

The city estimated that it lost $2 million a day in tax revenues because of the strike and a State official said that 60,000 workers were laid off because of the stoppage.

In another development, the Transit Authority, settled with unions representing 4,000 employees of the Long Island Railroad, the Nation's busiest commuter line. The 3-year pact, retroactive to January 1, 1979, provided for a 24-percent increase in wages over the term for seven unions. A total of 17 unions had been involved in protracted bargaining; 10 unions had settled earlier for a smaller wage increase. However, their contract had a "me too" clause guaranteeing them the same terms as those subsequently negotiated by the other unions. The railroad had been struck briefly by a Teamsters local, but the workers returned to heavy overtime scheduling during the New York City transit tieup.

Ford limits management pay increases

Ford Motor Co. has agreed to limit compensation increases of 5,000 nonunion management employees for 1 year to offset the amount by which the Council on Wage and Price Stability claimed the cost of the company's 1979 settlement with the Auto Workers exceeded the then prevailing 7-percent pay guideline. According to a council official, the average increase for the management employees will be held to "less than" the 7.5-percent low end of the current 7.5–9.5 percent guideline.

Ordinarily, a company is not permitted to make such an adjustment. However, Ford argued for an exception to the rule, saying that it could not offset the above-guidelines portion of the production workers agreement by holding down price increases because of "significant losses" on U.S. operations in 1979. General Motors Corp., which had settled with the UAW on the same terms as Ford, had earlier retained its right to bid on Government purchase contracts by agreeing to limit price boosts. (See *Monthly Labor Review*, February 1980, p. 13.)

Minneapolis food store employees settle

Settlements for 14,000 food store employees in the Minneapolis-St. Paul area provided for immediate wage increases of 15 to 17 percent and 11 percent in March 1981 and 1982. The three locals of the United Food and Commercial Workers first settled with Red Owl Stores to end a 3-day strike against that chain; National Tea Co. and various independent stores later accepted the same terms. About 325 stores were covered by the 3-year contracts.

The 15-percent initial pay increase for full-time meat cutters brought their maximum pay rate to $10.47 an hour. Maximum rates for full-time grocery clerks went to $9.71 as a result of a 17-percent increase. Full-time employees attain the top rate for their classification after 5 years of service. Part-time workers, who reach their top rate after 5,200 hours of work, received increases of 15, 11, and 11 percent on the respective dates, except for some "senior" part-timers who received $1 an hour increases in each year. The senior employees previously earned $6.33 and the other part-timers, $3.90 to $6.00. A rate schedule also was adopted for delicatessen employees similar to the rates for part-time workers in other departments.

The accords drew opposition from some members, who complained because the union had not won a primary goal, a cost-of-living wage escalator clause. Eugene Utecht, secretary-treasurer of Locals 653 and 653A and the chief union negotiator said that pay rates in the area were nevertheless among the highest in the Nation.

The employers won several changes that were expected to partly offset labor costs resulting from the contracts. Employers are now permitted to use scanning equipment for recording the price of an item indicated by the Universal Product Code markings. Previously, individual employers were required to negotiate with the union on introduction of scanners and some of the St. Paul stores had won limited use of such equipment.

Another gain permits employers to purchase precut boxed beef. Previously, they were required to purchase whole carcasses, which were then cut up in the meat departments.

Another change permits the stores to increase the ratio of part-time to full-time employees from 2 to 3. However, this can only be done through attrition; all current jobs are protected from conversion.

The normal monthly pension rate for each year of credited service was increased by $2 in each contract year. The resulting rates, which will reach $14 in the final year, will apply to future retirees and to current retirees who ceased work on or after July 1, 1971, because the 1977 settlement had included a commitment to provide matching pension rates for these current retirees.

Other contract changes included $12,000 life insurance for employees and $3,000 for the spouse, instead of the previous $9,000 and $1,000 coverage; a 100-percent increase in the optical benefit; addition of prescription drug coverage; and a $210-a-week sickness and accident benefit, instead of $125. □

Book Reviews

The evolution of collective bargaining

Collective Bargaining: Contemporary American Experience. Edited by Gerald G. Somers. Madison, Wis., Industrial Relations Research Association, 1980. 588 pp.

As the introduction to this important work implies, it may appropriately be assessed by comparison with its counterpart of 40 years ago, the Twentieth Century Fund study, *How Collective Bargaining Works.* Methodologically, the two works are very similar. Each is comprised of a series of independent chapters by various authors describing and analyzing the evolution and prevailing nature of collective bargaining on an industry basis. This volume, published by the Industrial Relations Research Association, covers 10 industries; its predecessor covered 14. In both cases, the authors had extensive research or practical experience or both in their respective industries and provided highly informative and realistic analyses of their subjects. Both works give the reader brief but enlightening descriptions of the economics of each industry, the historical development of the principal employer and union institution, the structure and processes of collective bargaining, and current policies, practices, and problems. Both also contain a general essay of a summary and overview nature—the Industrial Relations Research Association's essay by Jack Barbash coming at the end and the Twentieth Century Fund's essay by Philip Taft at the beginning. Each author, it may be noted, is a distinguished institutional economist and Industrial Relations Research Association president.

Even the limitations are similar. Both volumes (with a few notable exceptions) treat collective bargaining almost entirely in terms of contract negotiations. Contract administration and grievance handling are given scanty treatment. The informal day-to-day life of the workplace is, for the most part, ignored. Customary practice, fractional bargaining, and joint cooperation committees are largely passed over. These omissions are particularly unfortunate in the contemporary volume because of the extensive treatment of these and related subjects in the post-World War II literature. The absence of an index in the present work is also regrettable because of the wealth of detailed information it contains.

In comparing these studies, one can learn a great deal about the evolution of collective bargaining in the United States. The choice of industries for study is, in itself, revealing. Only four industries—bituminous coal mining, construction, steel, and electrical products—are treated in both volumes. The omission of the automobile industry from the Industrial Relations Research Association's volume is particularly surprising, although it may be attributable to the extensive literature that is available on this industry. (A statement explaining the basis of industry selection would have been helpful). The other essays are largely reflective of major historical changes. Trucking and airlines replace the railroads in transportation. Agriculture, hospitals, the postal service, and public education represent the areas of significant growth in collective bargaining during the post-World War II period. Chapters on other expanding sectors, like State and local government and retail food trade, would have been equally desirable, but space considerations may have been a reason for their omission.

However, the Twentieth Century Fund's chapters on anthracite coal, daily newspapers, book and job printing, men's clothing, hosiery, automobiles, rubber products, glass, and the Chicago service trades have not been replicated. Anthracite has become a nonindustry; the crafts of printing and publishing have been transformed by new technology; and the "model" unionism and collective bargaining in clothing have been victimized by foreign competition and relocation from the northeastern and midwestern metropolitan centers to the South. A case could have been made for their replication as a guide to understanding the shifting currents of collective bargaining. But the inclusion of both the expanding and declining bargaining sectors would have required a second volume.

The substantive content of the two studies also makes an interesting contrast. In 1940, collective bargaining reflected the dramatic rise of industrial unionism in the mass production industries and the resurgence of the old unionism in coal, clothing, construction, printing, and railroads. The tone everywhere was upbeat. Collective bargaining stood for dynamic change. By the end of the 1970's, collective bargaining was seen as institutionalized, bureaucratized, technically sophisticated, and under pressure even in the areas of expansion. Unionization was lagging behind growth in the labor force. Antiunion forces were growing in strength—as the failure of the Labor Law Reform Bill campaign revealed. Even such traditional centers of union strength, like construction, were experiencing a loss in job territories and industrial power centers like steel and autos were shrinking in size.

Jack Barbash concludes his summary essay with seven major issues which he describes as the "essences of the problems that have been raised throughout this work." In brief, these issues relate to (1) the ability of collective bargaining to adapt to adverse market conditions after a generation of expansion; (2) the limits of state intervention in collective bargaining; (3) the role of the state in minimizing the inflationary effects of collective bargaining; (4) the competing forces of centralization and decentralization; (5) public sector strikes; (6) occupational health and safety, and (7) racketeering and corruption in some unions. All are part of the problem of the exercise of power in a free society. These are perceptive and challenging issues. Others might be added such as the adjustment of individual or minority rights to collective interests and duties, and the capability of national institutions to cope with powerful international forces of competition and collaboration. All point to a future for collective bargaining that is, if anything, more challenging than the past 40 years.

A final note of tribute must be paid to Gerald G. Somers, who was the chief architect of the project, but who died before its completion. The quality of this work is a fitting testimony to his creative imagination and enterprise, known to all academic industrial relations specialists. We are indebted to Jack Barbash, Somers' colleague, and to Barbara Dennis, Industrial Relations Research Association editor, for the professional completion of the undertaking.

Not all jobs are created equal

Good Jobs, Bad Jobs, No Jobs. By Eli Ginzberg. Cambridge, Mass., Harvard University Press, 1979. 219 pp. $15.

This book is a collection of revised essays published between 1976 and 1979. The work is clearly intended for a general audience and is well written and free of technical jargon. The author, a professor of economics at Columbia University, is chairman of the National Commission for Employment Policy.

Eli Ginzberg's topic is a significant one. He has provided a broad overview of the American labor market. The central theme is that there is today a shortage of both jobs and good jobs. Ginzberg has estimated the number of potentially employable people to be 18 to 24 million, or 3 to 4 times the officially unemployed ones. Public and private employment cannot be expected to absorb more than a few million of this reserve force. While this may be so, a more detailed analysis of why it is so is in order. As for good jobs, less than one-third of such jobs were added since 1950 to the private sector. In contrast, two-thirds of government jobs are good ones.

From a theoretical perspective, the most important point by Ginzberg is that the economy is really a pluralistic one, with no less than one-third of all jobs in the not-for-profit sector, many of them in the service sector. This has facilitated a rapid growth of female employment, but also made it more difficult to secure gains in productivity.

For the 1980's, Ginzberg sees increasing competition among white males, women, and minorities for managerial and professional positions. Since the late 1960's, the labor market for highly educated persons has deteriorated and many have been forced to accept positions below their expectations. The resulting underemployment will lead to increasing disenchantment. This has been a recurrent theme in many of the writings on the labor market for educated people, but so far there is little evidence of it.

There are no prescriptions for a solution. This is somewhat of a disappointment, although the author does trace the development of labor policy. He also recognizes the increasing pressure on the Federal Government to provide jobs for more and more people.

All in all, this is a fine survey of the major labor market developments in the post-World War II period. Unlike Margaret S. Gordon, ed., *Higher Education and the Labor Market* (1974) and Richard B. Freeman, *The Overeducated American* (1976), Ginzberg has related the current labor market problems to broader economic developments. This is one of the greater strengths of his book. A bibliography of the relevant literature would have made the work even more useful.

The workplace as battleground

Workers' Control in America: Studies in the History of Work, Technology, and Labor Struggles. By David Montgomery. New York, Cambridge University Press, 1979. 189 pp. $14.95.

Robert Hoxie, in *Trade Unionism in the United States*, pointed out that "the essence of unionism is a social philosophy." David Montgomery's essays trace the impact of various social philosophies as their proponents vie for control of the workplace and of the rules which will govern employment, work pace, and method of payment. Although Montgomery favors the Socialist view, his quotations and analyses reveal some of the impacts of Hoxie's five functional types of unionism. As the author states in the introduction:

> No one knew better than the workers themselves that they needed a much better standard of living than they enjoyed, that only hard work and sound productive organization could produce such improvement, and that inefficiency and waste were built into the very fiber of the economic system. Their ideas of how to remedy the situation, however, were very different from those of their employers.

The first five chapters trace workers' efforts to retain or regain control over work rules from the late 1800's to the 1920's. Throughout the period, worker control of the workplace is eroded by industrialization, mass production techniques, immigration of workers with different control ideas, scientific management, paternalistic welfare schemes, as well as their own inability to select and support a social philosophy which will provide a significant counterforce to these massive social, economic, and managerial changes.

Chapter 6, coauthored by Ronald Schatz, and chapter 7 depart from the short period historical perspective and examine two topics over a longer timespan. The first deals with workers' attempts to restrict the use of layoff as a response to reduced demands for worker hours. The second is a dreary interpretation of the death of the labor movement and its replacement by "an immobile and isolated aggregation of legally certified bargaining agents." The attribution of this result to joint action by government and industry seeking a passive participant in the "moribund Capitalist system" is an indication of the polemic tone of these two chapters.

A closing bibliographical essay lists useful books and other sources for persons interested in delving further into worker control.

The book is a collection of essays with worker control as a unifying theme. Because the essays were meant to stand alone (only chapters 3 and 7 have not been previously published), this reviewer finds a disturbing amount of repetition of the setting, of management and worker views, and of the principal issues across the several essays.

Montgomery looks forward to the day when workers will "regain mastery over collective and socialized production". Although he does not show that they ever had such mastery, he does provide a revealing and sympathetic look at the struggle for control of their worklives in the face of dramatically changing conditions. He highlights the tension within unions as to whether their workplace power should be used for their own ends (Hoxie's business unionism) or to support the progress of the entire working class (Hoxie's uplift unionism). The essays underline the fundamental problem of achieving a consistent coalition among people whose self-interests and common interests only occasionally coincide. While the author blames the Capitalist and credit systems for keeping workers from gaining control of the workplace, the essays seem to illustrate that the question of *which* workers have control is often as important as *whether* workers have control.

The organizational view presented here is a strong contrast to the personal view presented by Robert Schrank in *Ten Thousand Working Days;* yet both are valuable perspectives on some of the same issues of worker control.

Current Labor Statistics

Notes on Current Labor Statistics 66

Schedule of release dates for major BLS statistical series 66

Employment data from household survey. Definitions and notes 67
1. Employment status of noninstitutional population, selected years, 1950–79 67
2. Employment status by sex, age, and race, seasonally adjusted 68
3. Selected employment indicators, seasonally adjusted 69
4. Selected unemployment indicators, seasonally adjusted 70
5. Unemployment rates, by sex and age, seasonally adjusted 71
6. Unemployed persons, by reason for unemployment, seasonally adjusted 71
7. Duration of unemployment, seasonally adjusted 71

Employment, hours, and earnings data from establishment surveys. Definitions and notes 72
8. Employment by industry, 1950–79 73
9. Employment by State 73
10. Employment by industry division and major manufacturing group 74
11. Employment by industry division and major manufacturing group, seasonally adjusted 75
12. Labor turnover rates in manufacturing, 1977 to date 76
13. Labor turnover rates in manufacturing, by major industry group 76
14. Hours and earnings, by industry division, 1948–79 77
15. Weekly hours, by industry division and major manufacturing group 78
16. Weekly hours, by industry division and major manufacturing group, seasonally adjusted 79
17. Hourly earnings, by industry division and major manufacturing group 80
18. Hourly Earnings Index, by industry division 80
19. Weekly earnings, by industry division and major manufacturing group 81
20. Gross and spendable weekly earnings in current and 1967 dollars, 1960 to date 82

Unemployment insurance data. Definitions and notes 83
21. Unemployment insurance and employment service operations 83

Price data. Definitions and notes 84
22. Consumer Price Indexes, 1967–79 85
23. Consumer Price Index, U.S. city average, general summary and selected items 85
24. Consumer Price Index, cross classification of region and population size class 91
25. Consumer Price Index, selected areas 92
26. Producer Price Indexes, by stage of processing 93
27. Producer Price Indexes, by commodity grouping 94
28. Producer Price Indexes, for special commodity groupings 96
29. Producer Price Indexes, by durability of product 96
30. Price indexes for the output of selected SIC industries 96

Productivity data. Definitions and notes 99
31. Indexes of productivity and related data, 1950–79 99
32. Annual percent change in productivity and related data, 1969–79 100
33. Indexes of productivity, hourly compensation, and unit costs 100
34. Percent change in productivity, hourly compensation, and unit costs 101

Labor-management data. Definitions and notes 102
35. Wage and benefit settlements in major collective bargaining units 102
36. Effective wage rate adjustments going into effect in major collective bargaining units 102
37. Work stoppages, 1947 to date 103

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics. A brief introduction to each group of tables provides definitions, notes on the data, sources, and other material usually found in footnotes.

Readers who need additional information are invited to consult the BLS regional offices listed on the inside front cover of this issue of the *Review*. Some general notes applicable to several series are given below.

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might otherwise mask short-term movements of the statistical series. Tables containing these data are identified as "seasonally adjusted." Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years. For a technical discussion of the method used to make seasonal adjustments, see "Appendix A. The BLS Seasonal Factor Method," *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), pp. 272–78, and *X-11 Variant of the Census Method II Seasonal Adjustment Program*, Technical Paper No. 15 (Bureau of the Census, 1967). Seasonally adjusted labor force data in tables 2–7 were last revised in the February 1980 issue of the *Review* to reflect the preceding year's experience. Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X-11/ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada Catalogue No. 12-564E, September 1979).

The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. Revisions of historical data continue to be made only at the end of each calendar year. Annual revision of the seasonally adjusted payroll data in tables 11, 13, 16, and 18 was last introduced in the November 1979 issue of the *Review*. New seasonal factors for productivity data in tables 33 and 34 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The resulting values are described as "real," "constant," or "1967" dollars.

Availability of information. Data that supplement the tables in this section are published by the Bureau of Labor Statistics in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule given below. The *Handbook of Labor Statistics 1978*, Bulletin 2000, provides more detailed data and greater historical coverage for most of the statistical series presented in the *Monthly Labor Review*. More information from the household and establishment surveys is provided in *Employment and Earnings*, a monthly publication of the Bureau, and in two comprehensive data books issued annually—*Employment and Earnings, United States* and *Employment and Earnings, States and Areas*. More detailed information on wages and other aspects of collective bargaining appears in the monthly periodical, *Current Wage Developments*. More detailed price information is published each month in the periodicals, the *CPI Detailed Report* and *Producer Prices and Price Indexes*.

Symbols

p = preliminary. To improve the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.

Schedule of release dates for major BLS statistical series

Title and frequency (monthly except where indicated)	Release date	Period covered	Release date	Period covered	MLR table number
Employment situation	June 6	May	July 3	June	1–11
Producer Price Indexes	June 6	May	July 8	June	26–30
Consumer Price Index	June 24	May	July 23	June	22–25
Real earnings	June 24	May	July 23	June	14–20
Work stoppages	June 30	May	July 29	June	37
Labor turnover in manufacturing	June 30	May	July 30	June	12–13
Major collective bargaining settlements (quarterly)	....	....	July 25	1st half	35–36
Productivity and costs (quarterly):					
Nonfarm business and manufacturing	....	....	July 28	2nd quarter	31–34

EMPLOYMENT DATA FROM THE HOUSEHOLD SURVEY

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 65,000 households beginning in January 1980, selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons are (1) those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population; the **total labor force** includes military personnel. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons retired, those engaged in their own housework, those not working while attending school, those unable to work because of longterm illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy.

Full-time workers are those employed at least 35 hours a week; **part-time workers** are those who work fewer hours. Workers on part-time schedules for economic reasons (such as slack work, terminating or starting a job during the week, material shortages, or inability to find full-time work) are among those counted as being on full-time status, under the assumption that they would be working full time if conditions permitted. The survey classifies unemployed persons in full-time or part-time status by their reported preferences for full-time or part-time work.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data presented in table 1. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 2–7 are seasonally adjusted, based on the seasonal experience through December 1979.

1. Employment status of the noninstitutional population, 16 years and over, selected years, 1950–79

[Numbers in thousands]

Year	Total noninstitutional population	Total labor force		Civilian labor force						Not in labor force
					Employed			Unemployed		
		Number	Percent of population	Total	Total	Agriculture	Nonagricultural industries	Number	Percent of labor force	
1950	106,645	63,858	59.9	62,208	58,918	7,160	51,758	3,288	5.3	42,787

EMPLOYMENT, HOURS, AND EARNINGS DATA FROM ESTABLISHMENT SURVEYS

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by 162,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

LABOR TURNOVER DATA in this section are compiled from personnel records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies. A sample of 40,000 establishments represents all industries in the manufacturing and mining sectors of the economy.

Definitions

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 14–20 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in transportation and public utilities, in wholesale and retail trade, in finance, insurance, and real estate, and in service industries. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to eliminate the effects of price change. The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries. **Spendable earnings** are earnings from which estimated social security and Federal income taxes have been deducted. The Bureau of Labor Statistics computes spendable earnings from gross weekly earnings for only two illustrative cases: (1) a worker with no dependents and (2) a married worker with three dependents.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

Labor turnover is the movement of all wage and salary workers from one employment status to another. **Accession rates** indicate the average number of persons added to a payroll in a given period per 100 employees; **separation rates** indicate the average number dropped from a payroll per 100 employees. Although month-to-month changes in employment can be calculated from the labor turnover data, the results are not comparable with employment data from the employment and payroll survey. The labor turnover survey measures changes during the calendar month while the employment and payroll survey measures changes from midmonth to midmonth.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of September 1979 data, published in the November 1979 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Complete comparable historical unadjusted and seasonally adjusted data are published in a Supplement to Employment and Earnings (unadjusted data from April 1977 through June 1979 and seasonally adjusted data from January 1974 through June 1979) and in *Employment and Earnings, United States, 1909–78*, BLS Bulletin 1312–11 (for prior periods).

Data on recalls were shown for the first time in tables 12 and 13 in the January 1978 issue of the *Review*. For a detailed discussion of the recalls series, along with historical data, see "New Series on Recalls from the Labor Turnover Survey," *Employment and Earnings*, December 1977, pp. 10–19.

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20. See also *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976).

The formulas used to construct the spendable average weekly earnings series reflect the latest provisions of the Federal income tax and social security tax laws. For the spendable average weekly earnings formulas for the years 1978–80, see *Employment and Earnings*, March 1980, pp. 10–11. Real earnings data are adjusted using the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

8. Employment by industry, 1950–79

NOTE: The earnings expressed in 1967 dollars have been adjusted for changes in price level as measured by the Bureau's Consumer Price Index for Urban Wage Earners and Clerical Workers.

These series are described in "The Spendable Earnings Series: A Technical Note on its Calculation," **Employment and Earnings and Monthly Report on the Labor Force**, February 1969, pp. 6–13. See also "Spendable Earnings Formulas, 1978–80," **Employment and Earnings**, March 1980, pp. 10–11.

UNEMPLOYMENT INSURANCE DATA

UNEMPLOYMENT INSURANCE DATA are compiled monthly by the Employment and Training Administration of the U.S. Department of Labor from records of State and Federal unemployment insurance claims filed and benefits paid. Railroad unemployment insurance data are prepared by the U.S. Railroad Retirement Board.

Definitions

Data for **all programs** represent an unduplicated count of insured unemployment under the State, Ex-Servicemen, and UCFE programs, and the Railroad Insurance Act.

Under both State and Federal unemployment insurance programs for civilian employees, insured workers must report the completion of at least 1 week of unemployment before they are defined as unemployed. Persons not covered by unemployment insurance (about one-third of the labor force) and those who have exhausted or not yet earned benefit rights are excluded from the scope of the survey. **Initial claims** are notices filed by persons in unemployment insurance programs to indicate they are out of work and wish to begin receiving compensation. A claimant who continued to be unemployed a full week is then counted in the insured unemployment figure. The **rate of insured unemployment** expresses the number of insured unemployed as a percent of the average insured employment in a 12-month period.

An **application** for benefits is filed by a railroad worker at the beginning of his first period of unemployment in a benefit year; no application is required for subsequent periods in the same year. **Number of payments** are payments made in 14-day registration periods. The **average amount of benefit payment** is an average for all compensable periods, not adjusted for recovery of overpayments or settlement of underpayments. However, **total benefits** paid have been adjusted.

21. Unemployment insurance and employment service operations

[All items except average benefits amounts are in thousands]

[1] Initial claims and State insured unemployment include data under the program for Puerto Rican sugarcane workers.

[2] Includes interstate claims for the Virgin Islands. Excludes transition claims under State programs.

[3] Excludes data on claims and payments made jointly with other programs.

[4] Includes the Virgin Islands. Excludes data on claims and payments made jointly with State programs.

[5] Cumulative total for fiscal year (October 1 - September 30).

NOTE: Data for Puerto Rico included. Dashes indicate data not available.

PRICE DATA

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Definitions

The Consumer Price Index is a monthly statistical measure of the average change in prices in a fixed market basket of goods and services. Effective with the January 1978 index, the Bureau of Labor Statistics began publishing CPI's for two groups of the population. One index, a new CPI for All Urban Consumers, covers 80 percent of the total noninstitutional population; and the other index, a revised CPI for Urban Wage Earners and Clerical Workers, covers about half the new index population. The All Urban Consumers index includes, in addition to wage earners and clerical workers, professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctor's and dentist's fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items is kept essentially unchanged between major revisions so that only price changes will be measured. Prices are collected from over 18,000 tenants, 24,000 retail establishments, and 18,000 housing units for property taxes in 85 urban areas across the country. All taxes directly associated with the purchase and use of items are included in the index. Because the CPI's are based on the expenditures of two population groups in 1972–73, they may not accurately reflect the experience of individual families and single persons with different buying habits.

Though the CPI is often called the "Cost-of-Living Index," it measures only price change, which is just one of several important factors affecting living costs. Area indexes do not measure differences in the level of prices among cities. They only measure the average change in prices for each area since the base period.

Producer Price Indexes measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes contains about 2,800 commodities and about 10,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The universe includes all commodities produced or imported for sale in commercial transactions in primary markets in the United States.

Producer Price Indexes can be organized by stage of processing or by commodity. The stage of processing structure organizes products by degree of fabrication (that is, finished goods, intermediate or semifinished goods, and crude materials). The commodity structure organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States, from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

In calculating Producer Price Indexes, price changes for the various commodities are averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage of processing groupings, commodity groupings, durability of product groupings, and a number of special composite groupings.

Price indexes for the output of selected SIC industries measure average price changes in commodities produced by particular industries, as defined in the *Standard Industrial Classification Manual 1972* (Washington, U.S. Office of Management and Budget, 1972). These indexes are derived from several price series, combined to match the economic activity of the specified industry and weighted by the value of shipments in the industry. They use data from comprehensive industrial censuses conducted by the U.S. Bureau of the Census and the U.S. Department of Agriculture.

Notes on the data

Beginning with the May 1978 issue of the *Review*, regional CPI's cross classified by population size, were introduced. These indexes will enable users in local areas for which an index is not published to get a better approximation of the CPI for their area by using the appropriate population size class measure for their region. The cross-classified indexes will be published bimonthly. (See table 24.)

For further details about the new and the revised indexes and a comparison of various aspects of these indexes with the old unrevised CPI, see *Facts About the Revised Consumer Price Index*, a pamphlet in the Consumer Price Index Revision 1978 series. See also *The Consumer Price Index: Concepts and Content Over the Years*. Report 517, revised edition (Bureau of Labor Statistics, May 1978).

For interarea comparisons of living costs at three hypothetical standards of living, see the family budget data published in the *Handbook of Labor Statistics, 1977*, Bulletin 1966 (Bureau of Labor Statistics, 1977), tables 122–133. Additional data and analysis on price changes are provided in the *CPI Detailed Report* and *Producer Prices and Price Indexes*, both monthly publications of the Bureau.

As of January 1976, the Wholesale Price Index (as it was then called) incorporated a revised weighting structure reflecting 1972 values of shipments. From January 1967 through December 1975, 1963 values of shipments were used as weights.

For a discussion of the general method of computing consumer, producer, and industry price indexes, see *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), chapters 13–15. See also John F. Early, "Improving the measurement of producer price change," *Monthly Labor Review*, April 1978, pp. 7–15. For industry prices, see also Bennett R. Moss, "Industry and Sector Price Indexes," *Monthly Labor Review*, August 1965, pp. 974–82.

[1] Prices for natural gas are lagged 1 month.

[2] Includes only domestic production.

[3] Most prices for refined petroleum products are lagged 1 month.

[4] Some prices for industrial chemicals are lagged 1 month.

[5] Data for December 1979 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

28. Producer Price Indexes, for special commodity groupings

[1967 = 100 unless otherwise specified]

Commodity grouping	Annual average 1978	1979									1980			
		Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.[1]	Jan.	Feb.	Mar.	Apr.
All commodities — less farm products	208.4	228.0	230.1	232.0	235.4	237.5	241.4	245.3	247.0	249.5	255.4	260.5	262.6	264.3

[2] Data for December 1979 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

PRODUCTIVITY DATA

PRODUCTIVITY DATA are compiled by the Bureau of Labor Statistics from establishment data and from estimates of compensation and output supplied by the U.S. Department of Commerce and the Federal Reserve Board.

Definitions

Output is the constant dollar gross domestic product produced in a given period. Indexes of **output per hour of labor input,** or labor productivity, measure the value of goods and services produced per hour of labor. **Compensation per hour** includes wages and salaries of employees plus employers' contributions for social insurance and private benefit plans. The data also include an estimate of wages, salaries, and supplementary payments for the self-employed, except for nonfinancial corporations, in which there are no self-employed. **Real compensation per hour** is compensation per hour adjusted by the Consumer Price Index for All Urban Consumers.

Unit labor cost measures the labor compensation cost required to produce one unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from the current dollar gross domestic product and dividing by output. In these tables, **Unit nonlabor costs** contain all the components of unit nonlabor payments except unit profits. **Unit profits** include corporate profits and inventory valuation adjustments per unit of output.

The **implicit price deflator** is derived by dividing the current dollar estimate of gross product by the constant dollar estimate, making the deflator, in effect, a price index for gross product of the sector reported.

The use of the term "man-hours" to identify the labor component of productivity and costs, in tables 31 through 34, has been discontinued. **Hours of all persons** is now used to describe the labor input of payroll workers, self-employed persons, and unpaid family workers. **Output per all-employee hour** is now used to describe labor productivity in nonfinancial corporations where there are no self-employed.

Notes on the data

In the private business sector and the nonfarm business sector, the basis for the output measure employed in the computation of output per hour is Gross Domestic Product rather than Gross National Product. Computation of hours includes estimates of nonfarm and farm proprietor hours.

Output data are supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are from the Bureau of Economic Analysis and the Bureau of Labor Statistics.

Beginning with the September 1976 issue of the *Review,* tables 31–34 were revised to reflect changeover to the new series—private business sector and nonfarm business sector—which differ from the previously published total private economy and nonfarm sector in that output imputed for owner-occupied dwellings and the household and institutions sectors, as well as the statistical discrepancy, are omitted. For a detailed explanation, see J. R. Norsworthy and L. J. Fulco, "New sector definitions for productivity series," *Monthly Labor Review,* October 1976, pages 40–42.

LABOR-MANAGEMENT DATA

MAJOR COLLECTIVE BARGAINING DATA are obtained from contracts on file at the Bureau of Labor Statistics, direct contact with the parties, and from secondary sources. Additional detail is published in *Current Wage Developments,* a monthly periodical of the Bureau. Data on work stoppages are based on confidential responses to questionnaires mailed by the Bureau of Labor Statistics to parties involved in work stoppages. Stoppages initially come to the attention of the Bureau from reports of Federal and State mediation agencies, newspapers, and union and industry publications.

Definitions

Data on wage changes apply to private nonfarm industry agreements covering 1,000 workers or more. Data on wage and benefit changes *combined* apply only to those agreements covering 5,000 workers or more. **First-year wage settlements** refer to pay changes going into effect within the first 12 months after the effective date of the agreement. **Changes over the life of the agreement** refer to total agreed upon settlements (exclusive of potential cost-of-living escalator adjustments) expressed at an average annual rate. **Wage-rate changes** are expressed as a percent of straight-time hourly earnings, while **wage and benefit changes** are expressed as a percent of total compensation.

Effective wage-rate adjustments going into effect in major bargaining units measure changes actually placed into effect during the reference period, whether the result of a newly negotiated increase, a deferred increase negotiated in an earlier year, or as a result of a cost-of-living escalator adjustment. Average adjustments are affected by workers receiving no adjustment, as well as by those receiving increases or decreases.

Work stoppages include all known strikes or lockouts involving six workers or more and lasting a full shift or longer. Data cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

35. Wage and benefit settlements in major collective bargaining units, 1975 to date

[In percent]

Sector and measure	Annual average					Quarterly average

How to order BLS publications

PERIODICALS

Order from (and make checks payable to) Superintendent of Documents, Washington, D.C. 20402. For foreign subscriptions, add 25 percent.

Monthly Labor Review. The oldest and most authoritative government research journal in economics and the social sciences. Current statistics, analysis, developments in industrial relations, court decisions, book reviews. $18 a year, single copy, $2.50.

Employment and Earnings. A comprehensive monthly report on employment, hours, earnings, and labor turnover by industry, area, occupation, et cetera $22 a year, single copy $2.75.

Occupational Outlook Quarterly. A popular periodical designed to help high school students and guidance counselors assess career opportunities. $6 for four issues, single copy $1.75.

Current Wage Developments. A monthly report about collective bargaining settlements and unilateral management decisions about wages and benefits; statistical summaries. $12 a year, single copy $1.35.

Producer Prices and Price Indexes. A comprehensive monthly report on price movements of both farm and industrial commodities, by industry and stage of processing. $17 a year, single copy $2.25.

CPI Detailed Report. A monthly periodical featuring detailed data and charts on the Consumer Price Index. $15 a year, single copy $2.25.

PRESS RELEASES

The Bureau's statistical series are made available to news media through press releases issued in Washington. Many of the releases also are available to the public upon request. Write: Bureau of Labor Statistics, Washington, D.C. 20212.

Regional. Each of the Bureau's eight regional offices publishes reports and press releases dealing with regional data. Single copies available free from the issuing regional office.

BULLETINS AND HANDBOOKS

About 140 bulletins and handbooks published each year are for sale by regional offices of the Bureau of Labor Statistics (see inside front cover) and by the Superintendent of Documents. Washington, D.C. 20402. Make checks payable to the Superintendent of Documents. Among the bulletins and handbooks currently in print are these:

Occupational Outlook Handbook, 1978–79 Edition. Bulletin 1955. A useful resource supplying valuable assistance to all persons seeking satisfying and productive employment. $8, paperback; $11 hard cover.

BLS Handbook of Labor Statistics 1978. Bulletin 2000. A 604-page volume of historical data on the major BLS statistical series. $9.50.

Handbook of Methods. Bulletin 1910. Brief technical account of each major statistical program of the Bureau of Labor Statistics. $3.50.

BLS Measures of Compensation. Bulletin 1941. An introduction to the various measures of employee compensation; describes each series, the manner in which it is developed, its uses and limitations. $2.75.

Occupational Projections and Training Data. Bulletin 2020. Presents both general and detailed information on the relationship between occupational requirements and training needs. (Updates Bulletin 1918 published in 1976.) $3.25.

Technological Change and its Labor Impact in Five Energy Industries. Bulletin 2005. A 64-page study appraising major technological change and discussing the impact of these changes on productivity and occupations over the next 5 to 10 years. $2.40.

BLS Publications, 1972–77. Bulletin 1990. A numerical listing and subject index of bulletins and reports issued by the Bureau from 1972 through 1977, supplementing Bulletin 1749, covering 1886–1971. $1.80.

International Comparisons of Unemployment. Bulletin 1979. Brings together all of the Bureau's work on international unemployment comparisons. Describes the methods of adjusting foreign unemployment rates in 8 countries to U.S. concepts. $3.50.

Productivity Indexes for Selected Industries, 1979 Edition. Bulletin 2054. A 190-page report of indexes of output, employment, and employee hours in selected industries from 1954 to 1978. This edition contains measures for three industries previously not covered, as well as components of previously published measures in 10 industries. $5.50.

Profiles of Occupational Pay: A Chartbook. Bulletin 2037. A graphic illustration of some of the factors that affect workers' earnings. This three-part presentation looks at wage variations among and within occupations and portrays characteristics of high- and low-paying urban areas and manufacturing industries. $3.50.

REPORTS AND PAMPHLETS

Single copies available free from the BLS regional offices or from the Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

How the Government Measures Unemployment. Report 505. A concise report providing a background for appraising developments in the area of unemployment.

Directory of BLS Studies in Industrial Relations 1960–78. Report 550. A listing of studies prepared by the Division of Industrial Relations as part of the Bureau's regular program of data collection and analysis in the field of industrial relations.

☆U.S. GOVERNMENT PRINTING OFFICE: 1980 O— 311-406/37

Handbook of Labor Statistics 1978

Handbook of Labor Statistics 1978
U.S. Department of Labor
Bureau of Labor Statistics
1979
Bulletin 2000

The 1978 edition of the Handbook of Labor Statistics makes available in one 620-page volume the major series produced by the Bureau of Labor Statistics. Each table is complete historically, beginning with the earliest reliable and consistent data and running through calendar year 1977. The volume includes index and technical notes.

Tables include:

Labor force
Employment
Unemployment
Hours
Productivity and unit labor costs
Compensation
Prices and living conditions
Unions and industrial relations
Foreign labor statistics
General economic data

Mail Order Form to:

NEWARK PUBLIC LIBRARY

U.S. DEPARTMENT OF LABOR
Ray Marshall, *Secretary*

BUREAU OF LABOR STATISTICS
Janet L. Norwood, *Commissioner*

The Monthly Labor Review is published by the Bureau of Labor Statistics of the U.S. Department of Labor. Communications on editoral matters should be addressed to the Editor-in-Chief, Monthly Labor Review, Bureau of Labor Statistics, Washington, D.C. 20212.
Phone: (202) 523 - 1327

Subscription price per year —
$18 domestic; $22.50 foreign.
Single copy $2.50.
Subscription prices and distribution policies for the Monthly Labor Review (ISSN 0098-0818) and other Government publications are set by the Government Printing Office, an agency of the U.S. Congress. Send correspondence on circulation and subscription matters (including address changes) to:
Superintendent of Documents,
Government Printing Office,
Washington, D.C. 20402

Make checks payable to
Superintendent of Documents.

The Secretary of Labor has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through October 31, 1982. Second-class postage paid at Riverdale, MD., and at additional mailing offices.

Library of Congress Catalog
Card Number 15 - 26485

July cover:

Ralph Fasanella's painting "Lawrence 1912: The Bread and Roses Strike," recalls the Massachusetts textile workers' strike during which young women, most of them recent immigrants, carried banners demanding "We want bread and roses too." District 1199, National Union of Hospital and Health Care Workers, AFL-CIO, has made the phrase the theme of its current cultural festival and has produced a full-color poster (21" × 35") of the Fasanella painting ($6, from District 1199 Cultural Center, Inc., 310 West 43 Street, New York, N.Y. 10036). The painting also appears as the cover illustration of William Cahn's book, *Lawrence 1919: The Bread and Roses Strike*, published by Pilgrim Press.

Labor Month In Review

EMPLOYEE BENEFITS. What employer-paid benefits do U.S. workers receive on the job? The Bureau of Labor Statistics has completed a pilot survey that provides some new answers. The survey covered 21 million employees of large and medium-sized firms in the private economy in 1979. BLS conducted the survey for the Federal Government's Office of Personnel Management which plans to use the data to estimate the cost of providing Federal workers similar benefits. (The BLS survey collected no cost data.) Some survey findings:

Paid holidays and vacations. Virtually all employees have paid holidays and paid vacations. Usually 9 to 11 holidays are provided each year, regardless of employees' length of service. The amount of vacation, however, generally varies by length of service. Typical vacation plans call for 5 days with less than 1 year of service; 10 days after 1 year; 15 days after 10 years; and 20 days after 15 years.

Sick leave plans. Formal sick leave plans cover 80 percent of the professional-administrative employees, 83 percent of the technical-clerical employees, and 37 percent of the production employees. The latter, however, are more frequently covered under accident and sickness insurance

Benefits differ significantly among the various sick leave plans, ranging from those providing 2 or 3 days of leave per year to others providing 6 months or more of benefits. Most plans provide full pay for at least a portion of sick leave.

Accident and sickness insurance. This insurance provides two-thirds of the employees with income during absence from work due to disability, sometimes in coordination with sick leave pay.

Just over half of the participants receive benefits for up to 26 weeks, and about one-fifth for up to 52 weeks. Professional-administrative and technical-clerical employees are more likely than production employees to be covered longer.

More than 80 percent of covered workers are in employer-paid plans.

Long-term disability insurance. Benefits from such plans replace some of the income workers lose due to disability. Generally, payments begin after sickness and accident insurance benefits are exhausted. Nearly half of all employees are participants in an employer-sponsored long-term disability plan. Potential benefits for more than three out of four plan participants equal more than half their usual earnings.

Nearly 80 percent of covered workers are in plans funded entirely by their employers.

Health insurance. Health insurance plans that are at least partially employer financed cover 97 percent of the workers in the survey. Nearly all participants are insured for hospital room and board, surgery, X-rays, and physician's hospital visits. One-half have some form of dental insurance, and almost one-fifth have vision care insurance.

Expenditures up to the usual rate for a semi-private room are covered for 90 percent of the participants with basic hospitalization plans. Other plans provide up to a specified amount for each day of hospital care. However, the number of insured hospital days is limited for 72 percent of all workers with hospital coverage, mostly to 365 days per hospital confinement.

Nine out of ten workers covered by major medical plans are insured to 80 percent of expenses (coinsurance). For nearly three-fourths of covered workers, all benefits are financed by their employers.

Pension plans. Eighty-seven percent of the employees participate in pension plans with either specified retirement benefits or with unspecified benefits based on employer contributions. The survey did not cover other plans that could provide retirement income, such as profit sharing, stock purchase, and savings plans.

More than two-fifths of all participants are covered by plans that require the employee to reach age 63 to 65 before being eligible to retire with immediate full benefits; the majority of these are in plans with no service requirements. Nearly one-fifth of participants are in plans specifying age 61 to 62 for normal retirement, and another fifth are in plans specifying age 60 or less.

Life insurance. Nearly all workers are provided life insurance by their employers. The amount of insurance usually varies by earnings and occupation. Sixty-three percent of all insured workers receive life insurance related to earnings. This includes 39 percent who are insured for a multiple of their annual earnings and 24 percent whose coverage is graduated according to an earnings schedule. A flat amount is provided to most of those whose insurance is not based on earnings.

A publication giving detailed tabulations from the level of benefits survey is in preparation. □

Worksharing in the U.S.: its prevalence and duration

Preserving jobs by shortening hours and spreading the work remains a relatively uncommon practice; the average duration of short-time work has apparently lengthened in recent years, but is still well below that of unemployment

ROBERT W. BEDNARZIK

Reduction of working hours, with accompanying pay cuts, during periods of economic downturn is a practice as old as the industrial era.[1] Under a "worksharing"[2] arrangement, pay and weekly hours are reduced so that all workers may be retained on the payroll. The advantages and disadvantages of worksharing are widely documented, centering on its use as an antirecessionary tool whereby the relative cost to employers of retaining workers or laying them off must be weighed.[3]

Advocates of worksharing argue that the system not only spreads the impact of a recession, but also fosters a higher degree of job attachment, keeps employment skills fresh, and allows workers to retain fringe benefits.[4] And, worksharing has been viewed as a way to maximize recent gains in employment of persons suffering the effects of past discrimination.[5] On the other hand, critics charge that worksharing, especially if government subsidized, discourages firms from adapting to technological and organizational changes, thus impeding the creation of new job opportunities. Furthermore, representatives of organized labor have expressed concern that worksharing may interfere with seniority privileges by cutting the wages of more highly paid senior workers.[6]

This article examines the incidence of worksharing in the United States; the time it takes a worksharer to return to a full-time schedule;[7] and various factors facilitating this change. The transition of worksharers to "not in the labor force," unemployed, and "other part-time" status is also examined. The data analyzed are from the Current Population Survey (CPS): regular annual average and gross flow statistics[8] and matched individual observations from May through August 1976, and between May 1976 and May 1977.[9] The probability that an individual will leave worksharing is hypothesized to depend on his or her human capital (training and experience), other income resources, and the value he or she attaches to nonmarket activities. The impact of these factors on the probabilities of remaining in worksharer status, finding or returning to full-time work, or making other labor market transitions is estimated using a multinomial logit analysis.[10]

A profile of the worksharer

In 1979, there were, on average, 1.6 million workers —1.8 percent of the total number of persons at work— involuntarily on shortened schedules because of slack

---

Robert W. Bednarzik is a labor economist in the Division of Employment and Unemployment Analysis, Bureau of Labor Statistics.

workloads. Demographically, blacks and women were disproportionately represented among this group, relative to their percentage of the working population. (See table 1.) Blacks, for example, made up 11 percent of the total at work, but accounted for 17 percent of all worksharers. Occupational attachment is another important factor in the extent of worksharing. In 1979, three-fourths of all short-time workers were concentrated in occupations other than white-collar, with the largest proportions of worksharers holding jobs as operatives (25 percent) and craft workers (16 percent). These percentages were higher than each occupational group's share of the total employed. The incidence of worksharing also varies by industry: construction and, to a lesser extent, the trade and manufacturing sectors account for disproportionate numbers of short-hours workers, because many jobs in these industries are seasonal in nature, and thus lend themselves to periodic cutbacks.

Worksharing and the business cycle

During the late 1950's and the early 1960's, the use of worksharing decreased as a means of forestalling layoffs in business cycle downturns. Thus, at the depth of the 1973–75 recession, the proportion of total nonfarm workers involuntarily on part-time schedules because of slack workloads was smaller than during the 1957–58 recession, and about the same as in the 1960–61 downturn. (See chart 1.)

Table 1. Worksharers by sex, race, occupation, and industry in comparison to the total at work population, 1979 annual averages

Selected characteristics	Worksharers	Total at work
Total: Number (in thousands)	1,602	91,287
Percent	100.0	100.0
Sex: Male	52.6	58.6
Female	47.4	41.4
Race: White	83.1	88.8
Black and other	16.9	11.2
Occupation:		
White-collar	25.2	50.9
Professional and technical	5.7	15.2
Managerial and administration	4.5	11.0
Sales	6.1	6.4
Clerical	8.9	18.3
Blue-collar	50.1	33.0
Craft and kindred	16.4	13.3
Operatives	24.6	14.9
Nonfarm laborers	9.1	4.8
Service	18.0	13.3
Farm	6.9	2.8
Industry:[1]		
Mining	0.9	1.0
Construction	14.9	6.1
Manufacturing	27.4	25.5
Transportation and public utilities	6.3	7.1
Trade	24.9	21.0
Finance, insurance, and real estate	3.2	6.3
Service	21.0	33.0

[1] Wage and salary workers, excluding agricultural and private household workers.

Contributing to this change was a decline in the proportion of collective bargaining agreements containing clauses calling for reduction of hours during slack periods. In the mid-1950's, about 1 in 4 collective bargaining agreements contained provisions for reduced hours in the event of an economic downturn, but by the mid-1970's, fewer than 1 in 5 major agreements included such clauses. This is consistent with the conclusion of a recent study of trade unions in U.S. manufacturing industries that "unions increase the use of layoffs by impeding the use of quits and cuts in real wages, while restraining firms' ability to reduce average hours worked and discharge employees."[11]

Although not as widespread as in some earlier downturns, worksharing arrangements were clearly evident in the 1973–75 recession. The number of persons employed part time involuntarily because of slack workloads peaked at 2.1 million in 1975, nearly twice the level of its low point in 1973. Despite subsequent economic recovery, the number of worksharers has remained at or above 1.5 million. Moreover, the 1975–79 recovery phase was the first such period during which the proportion of short-time workers did not fall below its prerecession low point. Either worksharers are remaining on shortened schedules for longer periods or employers are now using reduced hours to offset nonrecessionary production cutbacks.

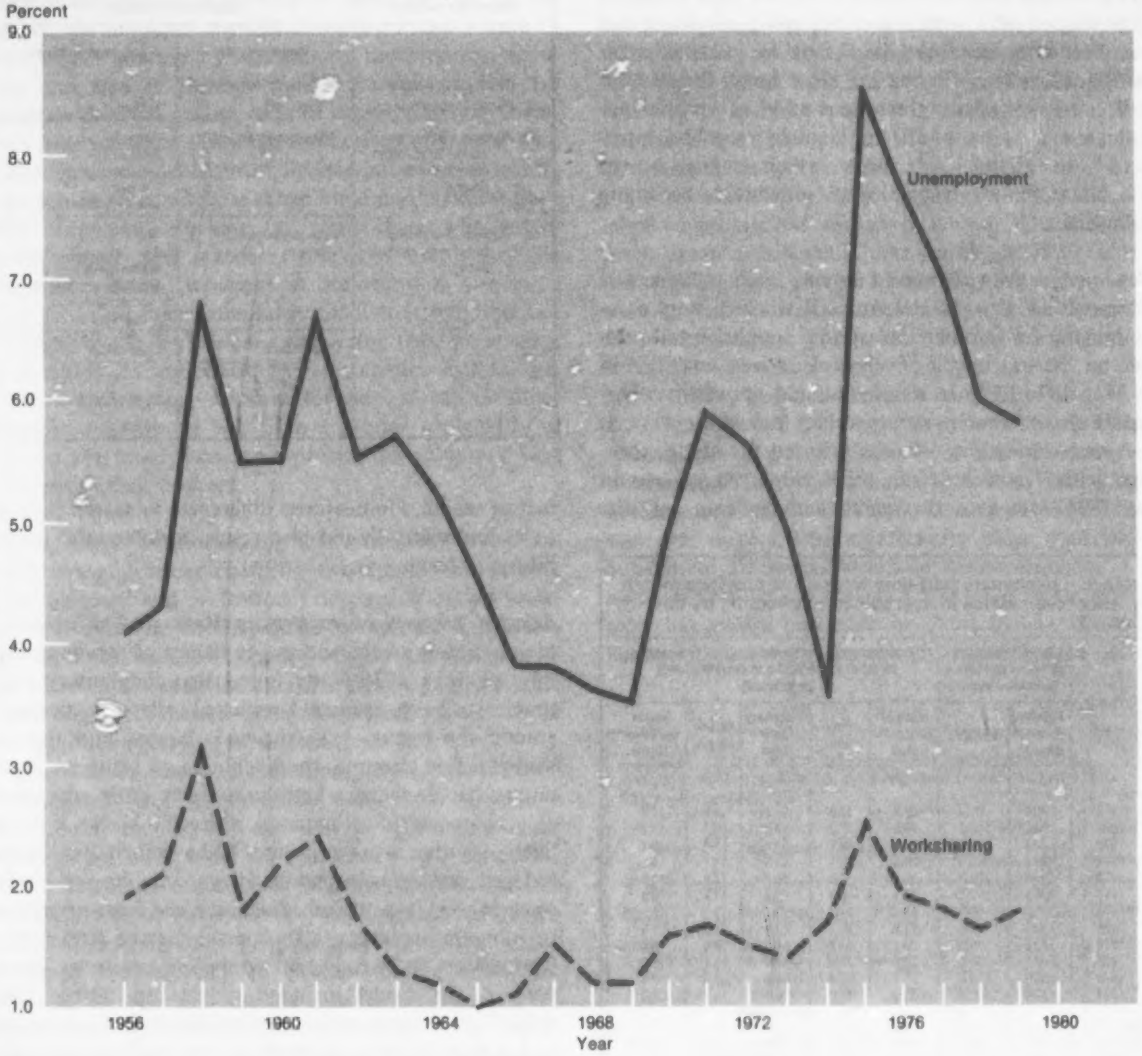
The data pertaining to all involuntary part-time workers depicted in table 2 support the "increased duration" hypothesis, showing a slight increase, between 1968 and 1979, in the probability of an involuntary part-timer remaining as such, on average, from one month to the next.[12] The increase was more prevalent among women than among men. Also, the increased likelihood of remaining involuntarily part time was accompanied by a corresponding 10-year decline in the percentage of involuntary part-timers finding or returning to full-time positions.

It should be noted that CPS data do not indicate if an actual job change occurred, but only that there was a change in labor force status between measurements. Consequently, we are unable to determine, for example, if a "worksharer to full-time" job transition was the result of a job change or of the restoration of the individual's regular weekly schedule in the same job. However, the primary concern of this article is the change in the worksharer's employment status, whether or not it involved a job change.

Changing employment status

A worksharer can, over a specific period, remain employed part time involuntarily, or alter his or her status by returning to or finding a full-time job, accepting other part-time employment, becoming unemployed, or dropping out of the labor force. For the purposes of

Chart 1. Trends in worksharing[1] and unemployment, 1956-1979 annual averages



[1] Involuntary part-time workers because of slack work as a percent of total at work.

this analysis, becoming unemployed and dropping out of the labor force were combined to form one transition; thus, there are four possible transitions. Movements into worksharing from full-time, part-time, and unemployed status will also be examined.

The tabulation in the next column presents the matrix of possible labor market transition, with each row or column representing an exhaustive list of entry or exit possibilities. For example, row I depicts the flow of persons who were involuntarily working part time (I) during the previous period (t-1) into continued worksharing (I), full-time employment (F), other part-time employment (P), or unemployment or "not in the labor force" (U), in the current period (t).

Employment status in previous period	*Flow possibilities*			
	I(t)	F(t)	P(t)	U(t)
I (t-1)	II	IF	IP	IU
F (t-1)	FI	FF	FP	FU
P (t-1)	PI	PF	PP	PU
U (t-1)	UI	UF	UP	UU

Causes of change in employment status

This section explores the factors that may influence the likelihood of a worksharer becoming employed full time, becoming employed part time for reasons other than slack work, or leaving the labor force. (See exhibit 1.) Because worksharing can be viewed as "partial unemployment," some of the explanatory variables introduced are similar to those which influence the probability of an unemployed individual becoming employed.

Job search activity. Foremost among such influences is job search activity. To determine if workers were actually looking for another job, special supplemental questions on the job search of all workers were included in the May 1976 CPS. It was found that approximately 9 percent of worksharers surveyed had looked for work at least once during the 4 weeks prior to the study, compared with 4 percent of all other employed persons in May 1976. However, the search data indicate only the fact of search. Unmeasured differences in search productivity and effort should also result in differential probabilities of leaving worksharing.

Exhibit 1. Summary of variables tested by worksharing logit model

Dependent variables	Independent variables	
	Model variable	Empirical measure
II (Remain a worksharer) IF (Return to a full-time job)	Job search-related: Searched	Looked
IP (Become a part-time worker for reasons other than worksharing)	Personal characteristics	Race Education Unskilled: Industry Union membership
IU (Become unemployed or not in the labor force)	Value of nonmarket activity	Age Sex Marital status Employment status of other household members
	Other factors: Unmeasured heterogeneity Rotation group controls	Usual status Rotation group dummies

Table 2. Involuntary part-time workers in previous month by labor force status in average current month, by sex, 1968–79

Year	Total involuntary part-time workers in previous month		Previous-month involuntary part-time workers by labor force status in current month (in percent)				
	Number (in thousands)	Percent	Involuntary part-time	Full-time	Voluntary part-time	Unemployed	Not in the labor force
Total:							
1968	1,924	100.0	25.3	44.0	13.7	5.9	11.2

Selected personal characteristics. Regarding other possible predictors of the success or failure of regaining full-time work, a 1976 study found that involuntary part-time work in general occurred disproportionately among the young, less educated, blacks, and the unskilled.[13] For example, the likelihood of being an involuntary part-timer was higher the lower one's educational attainment.[14] Furthermore, although blacks were as likely as other worker groups to have their workweeks reduced during an economic downturn, the restoration of their weekly work schedules was the least responsive to economic recovery.[15] To control for the tendency of worksharers to be found in blue-collar and service occupations, the model included a variable, termed "unskilled", to represent transport equipment operatives (other than drivers), laborers, service workers, and retail trade sales personnel.

Union membership status may also be important. Although unions' preference for layoffs over worksharing arrangements has increased, individual union members on worksharing arrangements would apparently have a greater likelihood of changing status than comparable nonunion workers. This may reflect the fact that union contracts frequently call for either layoff or restoration of usual weekly hours after a specified period of worksharing, depending on the economic position of the firm.

Nonmarket alternatives. It is important to note that an involuntary reduction in a person's usual weekly hours of work changes the attractiveness of his or her labor market options. The individual's initial decision to participate in the labor force on a full-time basis is based upon many factors. According to Jacob Mincer, for example, the marginal costs of home work and leisure to women are affected by age and by the presence, number, and ages of children in the household.[16] He also suggests that the employment of other household members may influence a woman's allocation of time among home, market, and leisure.[17] Because all of these factors and others enter into the labor force participation decision of persons working full time, those who subsequently have their schedules shortened may reevaluate their labor force participation according to the value they place on their nonmarket time. It is hypothesized that individual worksharers who value their nonmarket time highly (as indicated by characteristics such as age, sex, marital status, and employment status of other household members) will have a greater probability of leaving the labor force or switching to voluntary part time than other workers.

Other factors. Even assuming that individuals have constant probabilities of changing employment status over time, personal and professional differences among workers will influence the likelihood of specific individuals leaving worksharing.[18] Consequently, as the duration of the short-hours spell increases, a greater proportion of remaining worksharers consists of individuals whose probabilities of leaving worksharing are low.[19]

One way to control for this problem of unmeasured heterogeneity among individuals would be to include in the model the actual number of weeks individual worksharers have been on shortened work schedules. This information is not available in the CPS, but certain characteristics of worksharers which increase the probability of securing full-time jobs may be used as proxy variables. One characteristic which seems to indicate a tendency to leave worksharing is usual full-time or part-time status. For example, a comparison of the demographic, occupational, and industrial characteristics of all involuntary part-time workers with those of both voluntary part-time workers and full-time workers revealed that persons involuntarily on part-time schedules who are usually in such status have a close resemblance to voluntary part-timers and those who usually work full time characteristically resemble full-time workers.[20] The "usual status" variable was therefore included as a control for unmeasured heterogeneity.

Flow into and out of worksharing

Although the primary concern of this study was to analyze duration of worksharing and factors facilitating movement from it, flows into worksharing were also examined. This analysis provided insights into the reasons for an individual's entry into involuntary part-time status, and helped to predict and explain his or her next most likely labor market transition.

One-fourth of the worksharers in June 1976 were holdovers from the previous month. The largest inflow of newcomers to worksharing (54 percent) consisted of full-time workers who had their workweeks reduced, followed by persons previously unemployed or not in the labor force (27 percent), and entrants from other part-time status (19 percent).

In terms of demographic and labor market characteristics—age, marital status, race, sex, education, skill level, union membership, and search status (looking or not looking for another job)—newcomers to worksharing were generally similar to leavers, or the outflow from worksharing. (See table 3.) The one outstanding exception was union membership status, with newcomers less likely than leavers to be union members.

In contrast, stayers—persons who were worksharers in both May and June 1976—were different characteristically from leavers, particularly leavers returning to full-time schedules. Foremost among these differences was age; stayers were significantly older than leavers. Substantial differences were also evident in terms of sex, union membership status, and race; that is, stayers were more likely than leavers to be older, female, black, and nonunion members. Interestingly, the difference between

Table 3. Mean value of selected characteristics of stayers, newcomers to, and leavers from worksharing, May–June 1976

Variable	Description	Stayers	New-comers	Leavers		t-statistic[1]

[1] Means test of difference between stayers and leavers to full-time jobs.

[2] Unskilled includes the following detailed occupational categories: sales workers in retail trade, transport equipment workers other than drivers, all laborers, and service workers.

the numbers of stayers and leavers looking for another job was not significant; job search activity, as indicated by the job search variable, was not more typical of one group than of the other.

How successful were persons leaving worksharing in obtaining a full-time schedule? Nearly three-fifths of those leaving worksharing between May and June 1976 went to full-time schedules. As noted earlier, inflow to worksharing consisted predominantly of persons whose full-time schedules were cut back. Thus, the majority of the flows to and from worksharing were, as expected, persons moving into and out of full-time schedules. Departures to other part-time status, and to unemployment each accounted for about one-fifth of the leavers from worksharing.

Longitudinal data from the CPS

In addition to an analysis of change in employment status in 2 consecutive months, the design of the CPS also permits an examination of labor market flows over a 4-consecutive-month period, and between the same month in consecutive years. (See appendix for more detail.) Table 4 traces the labor market flow of persons on worksharing in May 1976 over the 3 following months, and between May 1976 and May 1977. Clearly, the percentage of worksharers in May 1976 remaining as such declined over the year: 27.4 percent still had worksharing arrangements 1 month later, while only 14.6 percent had the same status 1 year later.

It is probable, of course, that in the intervening periods, particularly the 12-month gap between May 1976 and 1977, persons classified as worksharers in both months had moved into and out of other labor force categories as well. Nevertheless, the data indicate that the vast majority of worksharers remain in involuntary part-time status for a relatively short time. For example, fewer than one-sixth of the worksharers in May 1976 were still on such schedules 3 months later.[21] Moreover, the majority of leavers returned to full-time jobs. The percentage who returned to full-time schedules tended to increase over time, from 45 percent 1 month later to 56 percent 3 months later.[22] But table 4 also reveals that, as time is extended, the percentage of worksharers leaving the labor force entirely becomes greater, perhaps indicating "discouragement" about finding a full-time job, or increased attractiveness of nonmarket activities. Apparently, the termination of worksharing for some individuals results from their simply abandoning the idea of securing a full-time schedule in the near future.

Table 4. Worksharers 16 years and over in May 1976, by labor force status in June, July, and August 1976, and in May 1977

NOTE: See appendix for discussion of limitations of CPS matched data.

Transition probabilities

Table 5 illustrates the probabilities of a change in employment status among selected groups of worksharers over a 1-month period. Although the results were generally consistent with the demographic makeup of all involuntary part-timers, there were a few surprises.

Older workers and married workers were most likely to remain worksharers, while newcomers to worksharing—persons reporting their usual status as full time—were least likely to do so. The average duration of worksharing was 6.7 weeks for older workers, compared with 5.5 weeks for newcomers to worksharing.[23] The average duration of worksharing for all persons on such schedules was 6 weeks, roughly half the mean duration of unemployment over the same period.

An individual's usual full- or part-time status was a strong predictor of his or her likelihood of finding or returning to a full-time job. Worksharers whose schedules were usually part time were less than half as likely to move into full-time status as were those who usually worked full time.

Age and race also significantly influenced the "worksharing to full-time" job transition. Younger workers had a higher probability than older workers of making such a move, and whites were nearly twice as likely to secure full-time employment as were blacks. One possible explanation of the difference noted between age groups involves a contrast between the duration of any worksharing spell, and the number of such spells incurred. Among the unemployed, for example, younger workers have more frequent spells of unemployment than older workers, but the duration of each spell is shorter. The partial evidence indicates that this could also be the case for young worksharers.

Younger worksharers were much less likely than those who were older to become unemployed or to leave the labor force. Older or more senior workers may prefer layoff over a shortened workweek because they are more likely to be eligible for unemployment insurance benefits, and may be entitled to supplemental unemployment benefits as well. Thus, financially, the difference between unemployment and worksharing may not be as significant to older workers. Also, older workers may not feel as threatened by layoff and the prospects of a job loss as younger workers because their seniority usually ensures their recall to work.

There was some marginal evidence that union worksharers have a higher probability of returning to full-time status than worksharers who were not union members, perhaps because the latter are less likely to be governed by a given set of procedures for reductions in hours. Worksharers who were union members also were somewhat less likely than others to be laid off or to leave the labor force. This could be related to the fact that union members are unlikely to suffer a cutback in weekly hours unless the expected duration is short. "If . . . it is known that manpower needs will be curtailed for a lengthy period," notes one observer, "the union may prefer to bypass the reduced hours provisions and initiate layoffs immediately."[24]

Surprisingly, the fact that an individual looked for another job while on a shortened workweek did not affect the probability of his or her leaving to take a full-time job. Because search activity increases the probability of an unemployed person obtaining employment[25], it was also expected to increase a worksharer's chances of securing a full-time position. Apparently, the key is the intensity of the search effort, which could not be determined from survey results. Perhaps search effort among worksharers is not as intensive as among the unemployed. There is a similarity between involuntary part-time work due to slack workloads and temporary layoffs. Workers often know in advance that the duration of their reduced work schedule is likely to be relatively short, and thus are not generally inclined to look diligently for another job. Other worker characteristics which did not significantly affect transitions into and from worksharing status were educational attainment, and the presence of other employed family members.[26]

Conclusion

Unlike policymakers in most Western European nations, those in the United States have not to date given much attention to arrangements affecting the supply of labor, including worksharing.[27] Because of present Federal regulations and collective bargaining agreements, it is most often in the employer's interest to resort to layoffs instead of a reduction in hours. In most cases, for example, fringe benefit costs alone would be larger under a worksharing system, because there are few, if any, such costs associated with workers on layoffs.

Table 5. Monthly probabilities of change in labor force status, by selected worker characteristics

Probability:	Full sample	Usual status		Age [1]		Marital status		Race		Sex		Education [1]		Skill level		Union status		Job search	
		Full-time	Part-time	24 years	53 years	Married, spouse present	Other	White	Black and other	Male	Female	8 years	14 years	Skilled	Unskilled	Union member	Nonunion member	Looked	Did not look

Sum of probabilities . . .	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

[1] Years reflect the standard deviation above and below the mean.

[2] Includes all voluntary part-time workers and involuntary part-time workers because of material shortages, "started or ended a job during the survey week", or "could only find part-time work."

NOTE: Transition probabilities are calculated from derivatives obtained in the logit analysis which reveal the marginal effect of a change in the independent variable on the absolute probability of a given transition in labor force status, in the vicinity of sample means: $\text{Probability}_{p} \mid x_{s} = 0 =$ (full sample probability_{pk} − derivative_{jk} × mean_{j}); $\text{Probability}_{p} \mid x_{s} = 1 =$ ($\text{Probability}_{p} \mid x_{s} = 0 + \text{derivative}_{jk}$); where j = independent variable and k = dependent variable, and the sum of the $\text{probabilities}_{p} = 1$. The probabilities shown are based on the logit estimates presented in the appendix to this article.

Due to rounding, sums of individual items may not equal totals.

Another major roadblock to worksharing is the unemployment insurance system, which may actually lead workers and their unions to accept layoffs as opposed to reduced hours. Workers whose hours are cut receive no compensation from the State (except in California), unless their earnings fall below the level of benefits to which they would be entitled in a layoff.

Worksharing arrangements as a means of saving jobs will bear close watching in coming years. Of special interest is the recently enacted California "Work Sharing Unemployment Insurance" program, which allows transfer payments, in the form of unemployment insurance benefits, to persons whose wages and hours are reduced as a temporary alternative to layoffs.[28] (See following article.) Benefits are paid as a proportion of the maximum benefit available to an individual for a given week if the lost time is equal to or greater than some established minimum worktime reduction. For example, a worker eligible to receive a maximum of $100 in weekly benefits could receive about one-fifth of that amount, or $20, for every full day of lost work.[29] The California program and a wide-scale pilot project throughout Canada are being cautiously evaluated for their impact on unemployment and patterns of labor force participation, and for other economic and social effects on firms and employees.[30] ☐

[2] Worksharers are herein defined as employed persons whose workweeks have been reduced below 35 hours due to slack workloads. As such, they are a subset of the larger "part-time for economic reasons" group, which also includes persons on reduced hours because of material shortages, repairs to plant or equipment, start or termination of job during the survey week, and unavailability of full-time work.

Other methods of worksharing, such as increasing unpaid leave or the number of annual holidays, or reducing the amount of overtime worked, are excluded from the scope of this article.

[7] Heretofore, little was known about the length of time worker groups involuntarily on worksharing must "share the work." The cost of any government-assisted short-time compensation program is directly related to the length of time an individual worker could expect to receive such compensation. The limited information previously available on reduced worktime arrangements in Germany and California reveals that duration in such status is relatively short—under 3 months in Germany, and less than 5 weeks in California. See Fred Best and James Mattesich, "Short-time Compensation and Work Sharing: A New Alternative to Layoffs, *Special Report* (California Employment Development Department, 1979), pp. 14–25.

[8] Gross change data, a byproduct of the CPS, show the labor force status of persons not only for the current month, but also for the previous month. The data thus permit the identification and measurement of the flow of persons who leave involuntary part-time work from one month to the next. Gross changes, therefore, represent a short-run "flow," rather than a "stock," of a particular labor force group.

[9] Matched CPS data were chosen over the National Longitudinal Survey (NLS) and the Panel Study on Income Dynamics (PSID) primarily because of the greater sample size available from the CPS. The sample size quickly becomes the limiting factor when a situation experienced by only a small portion of individuals over a relatively short period is considered. The focal point of this analysis is the May 1976–May 1977 period because (1) the May 1976 CPS questionnaire contained a special supplement on job search by workers, and (2) the percentage of the "at work" population on worksharing was fairly steady during this period.

[21] The 3-months-later flow is based upon two rotation groups with the assumption that one rotation group does not differ much from any other. Although each rotation group is in itself a probability sample, responses differ across groups. This is commonly known as rotation group bias and is discussed more fully in the appendix. Thus, the standard error of the one-sixth figure is unknown. Generally, however, the error would not alter the fact that a person's stay on worksharing declines fairly quickly over a 1-year period.

[22] Although rotation group bias also affects these percentages, the bias, in general, would not be likely to cause the direction and distribution of worksharers' flows over time to defy economic logic.

[23] The expected duration of worksharing for the typical individual can be computed by $1/1\text{-}P_i$, where P_i is equal to the probability of staying a worksharer, given variable i. One must assume that $1\text{-}P_i$, the mean escape rate, is constant for each individual over time.

[25] Barron and Mellow, "Changes in Labor Force Status Among the Unemployed."

[26] Because the employment status of other family members is in itself a very limited proxy for other income sources, and the proportion of multi-earner families varies considerably by age of secondary earner, the interpretation of the impact of such a variable is difficult. Therefore, the "employment status of other family members" variable was deleted from the final logit regression run.

APPENDIX

Limitations of the matched data

Any survey procedure has inherent within it both sampling variability and response variability. The Current Population Survey (CPS) obtains its longitudinal flavor from the 4-8-4 rotation group design; the sample is divided equally into 8 rotating groups of households. Each group is in the sample for 4 months, out for 8, and then back in for 4. Consequently, 6 of the 8 groups are common in 2 consecutive months. A further reduction in the match data available results from the fact that identical persons must be matched in order to compute gross information. Since the basis for selection of the CPS sample is household units rather than individuals, common rotation groups reflect identical households but not necessarily identical persons. In any 2-month period, for example, the six common rotation groups will contain a number of persons who have moved from households in the sample area (about 1.5 percent per month) and noninterview cases (4 to 5 percent per month)—persons who refuse to respond and those absent from home during the interview week. The exclusion of nonidenticals not only affects the size of the sample available, but also may introduce a special bias in matched estimates, because the nonidentical persons excluded may differ from those of identical persons.

To evaluate the primary match used in this study, the mean values of selected demographic characteristics for the May–June 1976 match sample for all worksharers and for all involuntary part-time workers in May 1976 are provided below:

Variable	*May–June 1976 match sample of all worksharers*	*May 1976*	
		All worksharers	*All involuntary part-timers*
Age (years)	38	N. A.	35
Married, spouse present	.63	N. A.	.51
Black and other	.17	.18	.18
Female	.46	.43	.49

N. A. = Not Available

The tabulation shows that the demographic composition of the matched sample was generally similar to the larger populations of all worksharers and all involuntary part-time workers. This lends some credence to the representativeness of the May–June 1976 match utilized in this study.

Response variability occurs in the form of misclassification of reported labor force status and in "rotation group bias." The "net errors" between the original and reinterview results are comparatively small because of offsetting differences, but gross differences may be substantial. The second form of response variability, "rota-

[1] Unskilled includes the following detailed occupational categories: sales workers in retail trade, transport equipment workers other than drivers, all laborers, and service workers.

tion group bias," is related to the rotation group structure of the CPS sample mentioned earlier. The response of persons interviewed varies by month in sample. This is due in part to sampling variability. However, the two dominant explanations for this phenomenon are that differential attrition changes the distribution and composition of the sample, and that participation in the survey itself conditions or alters subsequent responses.

To control for the second problem, dummy variables indicating which month the individual was in the sample were included as explanatory variables. No attempt was made to control for the problem of different reinterview probabilities, although this problem should be somewhat mitigated by the demographic similarities between the matched sample and the total population of worksharers.

Basis of estimates of transitional probabilities

Exhibit A-1 presents the maximum likelihood estimates from the logit analysis, with associated asymptotic t-statistics, and derivatives (at sample means), which provided the basis for the transitional probabilities shown in table 5. All independent variables were constructed from the May 1976 CPS data; dependent variables were defined on data from the June 1976 CPS. The sample size was 475, and the χ^2 statistic, which tests the hypothesis that all parameters except the constants were zero, was 95.8, with 42 degrees of freedom.

Short-time compensation systems in California and Europe

Preliminary analysis of the available data on California's "Work Sharing Unemployment Insurance," enacted to prevent layoffs after passage of Proposition 13, suggests the program worked well; more analysis is needed for a final judgment

FRED BEST AND JAMES MATTESICH

During times of high unemployment it is often suggested that work time be reduced in order to spread available jobs among a larger number of persons. Numerous proposals have been advanced in this area, but only a few hold promise as effective employment policies.[1] One of these is "short-time compensation." This proposal provides partial unemployment insurance benefits for work time lost by employees who have taken a reduction in work hours to prevent layoffs or dismissals by their employer.

As a rough illustration: if a firm were to reduce employees' workweeks and pay levels by 20 percent rather than laying off 20 percent of its employees, those employees working short time would receive 20 percent of weekly unemployment insurance benefits. Thus, employees on reduced workweeks would be partially reimbursed for lost earnings and workers would not lose their jobs.

This article explores this approach to combating joblessness by reviewing the history of the "short-time" compensation concept in the United States and examining the operation of a recently initiated program in California against a backdrop of comparable European programs.

Background of the concept

Short-time compensation programs have been widespread and reportedly successful in several European nations since the 1920's but the U.S. unemployment insurance system was not used for such purposes until 1978. Many U.S. unemployment insurance programs have provisions for paying partial benefits for less than a full week of unemployment,[2] but such benefits are limited roughly to the differences between full weekly benefits and the income earned during the week in question. For example, if an employee earns $250 for a 40-hour workweek and is eligible to receive $100 in benefits for a week of unemployment, he or she could not receive benefits for working say a 32-hour week because earnings for more than 2 days of employment would total more than $100. Thus partial benefits are not suitable as a worksharing policy.

By contrast, under short-time compensation, unemployment insurance benefits would be paid as a proportion of the maximum benefits available to a worker for a given week if the lost time equals or surpasses an established minimum work time reduction. Thus, a worker eligible to receive a maximum of $100 in weekly benefits could receive about one-fifth that amount or $20 for every full day of lost work.

Recent consideration of using short-time compensation within the United States began as a response to the aggravated unemployment problems of New York City in 1975.[3] The so-called "Poses Plan" was suggested both to reduce joblessness and to minimize loss of affirmative action gains by preventing the layoff or dismissal of recently hired minority workers.[4] In March 1976, a bill was introduced to the New York State Assembly to allow unemployment insurance benefits to be paid on a daily rather than weekly basis[5] but died in committee. (About the same time, Canada implemented a limited pilot study of the short-time compensation concept).[6]

Federal Government interest in short-time compensation has progressed slowly. During 1978 and 1979, the U.S. Department of Labor established a special task force to monitor existing programs, make preliminary assessments of the concept, and explore the possibility of funding a pilot study.[7] Most recently, members of Congress have indicated an intention to introduce legislation to support development of the program.[8]

Independent of Federal and other initiatives, California examined the concept,[9] then established an experimental statewide program during mid-1978[10] in response to expected public employee unemployment re-

sulting from passage of Proposition 13. The program was rapidly implemented, and although the widespread layoffs expected from Proposition 13 did not materialize, the program has been continued. Although other States have the discretion to establish similar programs, as of early this year, the California program is the only one of its type in the United States.

The California program

California's "Work Sharing Unemployment Insurance" program began as an 18-month experiment and was extended in July 1979 for an additional two years. The basic design is similar to programs which have existed in Europe for several decades. It is operated by the California Employment Development Department, which administers unemployment insurance, disability insurance, and the California State Employment Service.

The legislation creating the program provides that an employer facing a drop in business may choose, instead of layoffs, to reduce the hours and wages of all or a designated part of the work force and share the remaining work among the employees. The reduction must involve not less than 10 percent of the employer's regular permanent work force in the affected work unit or units. In addition, the hours and wages of the affected employees must be reduced by 10 percent or more because the program would be only minimally effective but administratively expensive, at a lower reduction in hours. Each employee included in the program is eligible to receive a weekly unemployment insurance benefit proportional to the percentage reduction in wages and hours.

The program was designed to operate within the existing California unemployment insurance system. Each participating employee must meet basic UI eligibility requirements. In California, these requirements are relatively liberal. Before 1980, a worker must have earned at least $750 in wages during the 12-month "base period" prior to receiving benefits (increased to $900 in 1980). That amount of earnings would provide, however, only minimal regular unemployment insurance weekly benefits of $31. Prior to 1980, the weekly ceiling for unemployment insurance benefits was $104 ($120 in 1980) if the recipient earned $3,308 ($4,160 in 1980) or more in the highest quarter of his or her base period. Thus a worker who is eligible for maximum weekly benefits would receive $21 ($24 in 1980) for each work day lost.

The California legislation allows the payment of worksharing benefits to each participating employee for up to 20 weeks during a 52-week period beginning with the first week benefits are paid. If the 20 weeks are exhausted and workers are then laid off, those who lose their jobs would be eligible for regular unemployment insurance benefits with the duration reduced slightly to reflect the dollar costs of the worksharing benefits already received.

The Work Sharing Unemployment Insurance program was also designed to interefere as little as possible with existing labor-management relationships. Employers' participation in the shared work program is strictly voluntary. However, if participating employees are covered by a collective bargaining agreement, their union must agree to the plan. Of course, where no agreement exists, the employer is free to decide whether to participate or not. Thus far, there have been no signs of employee resistance to the program in participating firms.

Employers participating in the California program are charged for benefits in the same manner they are charged for regular unemployment insurance benefits. However, participating employers, whose recent history of unemployment insurance benefit charges exceed their contributions ("negative reserve employers"), are required to pay additional unemployment insurance taxes ranging from .5 percent to .3 percent on the first $6,000 of all employee wages, in succeeding calendar years. These tax increases are intended to discourage use of the program by firms which normally make seasonal layoffs.

To encourage employer participation and to keep "bureaucratic red tape" to a minimum, administration of the program has been kept simple. Employers are only required to call or write for a two-page application form, provide basic employee identifying information, state that work-time reductions are economically necessary and submit information on the amount of wage and hour reductions. If the application for Work Sharing Unemployment Insurance is approved, employers provide their participating employees with a weekly statement of reduced hours and wages which employees then use to claim "shared work" benefits.

The program is intended to prevent layoffs. However, California employers are not required to "document" or prove that a reduction in hours cannot be avoided. Nor are employers prevented from laying off some workers before or after beginning the program. The question of continuation of fringe benefits (health insurance, retirement, etc.) is not addressed in the California legislation and therefore is left to each employer. No restrictions are placed upon the employers' operation of their businesses, including discharges, transfers, and new hires. In addition, the number of participants, as well as the original wage and hour reduction assigned by the employer may be easily changed by means of written notification to the Employment Development Department.

Restrictions on workers who participate are also kept to a minimum. Workers receive their shared work benefits directly from the State by mail. However, an initial claim must be filed personally by each worker at a local branch office of the Employment Development Department. The benefits are not taxable under California law but are taxable, to the same extent regular unemployment insurance benefits are, under Federal law.[12]

One restriction on outside or extra work does exist: workers who either "moonlight" or perform work in excess of the "reduced" hours assigned by their employers have such earnings deducted from their shared work benefits.

Workers whose employers have stated that the shared work plan will be used as a temporary measure (defined as fewer than 10 weeks) are automatically exempted from the normal work search requirements that regular unemployment insurance recipients must meet. Employers who state that their expected downturn will last longer than 10 weeks but who believe that the downturn is nevertheless "temporary" in nature may also have their employees exempted from work search requirements simply by providing an explanation as to why they believe the downturn will be temporary. If, however, an employer, who is expecting a permanent work force reduction, uses the shared work program as a transitional mechanism which allows employees to look for other employment while working reduced work hours, those workers receiving benefits must meet the work search requirements of the regular unemployment insurance system. During the first 15 months of the program's existence, only one employer with five workers has used the program in this fashion.

The California program is not widely known. Between July 1978 and the end of September 1979, 312 employers had approved worksharing compensation plans, covering 7,603 employees. Some 3,165 of these employees filed claims and received, on the average, $23.63 per week for an average of 4.85 weeks. The average number of total dollars paid to worksharing recipients was $114.65 and the total amount paid in worksharing benefits up to September 1979 was $263,698.

Use of the program grew slowly at first, with only 67 firms receiving certification between July 1978 and February 1979. However, participation has accelerated with the total number of certified firms increasing to 701 by April 1980. It is commonly assumed that lack of early use and subsequent increases in participation can be largely attributed to gradual growth of awareness of the program. Nonetheless, when one considers that there are over 500,000 firms and 10 million workers in California, it is apparent that the program has thus far been used by a very small number of employers.

The low level of participation and the quality of the data currently available preclude any definitive assessments of the worksharing program at this time. However, existing information can provide some provisional indications. Some 33 percent of certified California firms were in manufacturing and 14.1 percent were in wholesale and retail trade and services. (See table 1.) Over 75 percent of the 3,165 workers who filed claims for shared work benefits were employed by firms in manufacturing, in contrast to 28.5 percent of workers making regular unemployment claims. (See table 2.)

The relative size of firms participating in the program has been small so far. Roughly 85 percent of participating firms had fewer than 40 employees drawing benefits and only four firms had over 200 employees. (See table 1.)

The typical reduction in workweek and wages used by participating firms in California was 20 percent. About two-thirds of those participating went from 5- to 4-day weeks. About 6 percent of participating employers chose a 10-percent work-time reduction, while 28 percent chose reductions of 30 percent or more. (See table 1.) Only 5 of the 312 certified firms as of September 1979 involved workers with standard workweeks under 35 hours.

Many employers have chosen to apply the reductions only to a portion of their work force. The 312 employers using the program through September of last year employed 14,273 workers, but only 7,603 employees

[2] UI Claimant Characteristics Study, July 1, 1976 and June 30, 1977. Employment Data and Research Division, California Employment Development Department, is the source (January 1979).

were included in the program. In this group, unionized firms had 4,587 employees but only 1,294 were certified to use the program. Also, it appears that significant portions of work forces not included in the program may be salaried and white-collar employees who are not commonly laid off, or members of units working at full staff.[13]

It is particularly noteworthy that California firms which have thus far utilized worksharing unemployment compensation appear to have healthier unemployment insurance tax accounts than those using regular layoffs. Over 78 percent of the firms participating in the program had account status in which tax contributions to unemployment insurance have been greater than withdrawals in contrast to 63 percent of other firms. This suggests that the program may not be unduly subsidizing seasonal employers, and that the program's special surtax provides a disincentive to participation by such firms.

Of the 7,603 workers approved to receive Work Sharing Unemployment Insurance benefits by September 1979, only 3,165 actually filed claims. Preliminary indications are that many employers who believed that they would have to lay off workers or cut workweeks obtained certification for benefits but ultimately found its use unnecessary. In addition, it appears that a significant proportion of employees within firms using the program have failed to submit their claims for benefits.

The incidence of union affiliation has so far been higher among benefit claimants than among workers claiming regular unemployment benefits. That is, 25.8 percent of the workers claiming shared work benefits up to September 1979 were unionized as compared to 16.5 percent of regular benefit claimants. While this issue requires more detailed assessment, it would appear that unionization has not deterred participation.

No clear picture emerges from breakdowns of shared work benefit claimant data by age, race, and sex. The proportion of younger workers is lower among worksharing unemployment claimants than among regular unemployment claimants, indicating that junior workers are retained rather than laid off. Breakdowns by race and sex are puzzling. If minorities and women are laid off before other employees, their proportions should be higher among those claiming regular unemployment benefits than among those claiming worksharing benefits. Curiously, there is little difference by sex, and the proportion of minority workers using worksharing benefits is higher than the proportion using regular unemployment benefits. These figures could indicate that the new program is used more among firms with high proportions of minority and women workers, or that many minorities and women are ineligible for unemployment insurance, or that there are inaccuracies in the available data.[14] More detailed analysis will be necessary to assess the implications of Work Sharing Unemployment Insurance for affirmative action programs.

In addition to statistics, opionions were collected from representatives of participating firms and unions to get some indication of how the program had been received. Early in December 1979, representatives from 30 firms which actually used the program were interviewed by phone. Of these firms, 25 strongly favored the program and 5 were neutral. Firm representatives favored the program because it helped them retain valued employees, was generally appreciated by workers, and was easy and flexible to administer. Representatives from 20 of the 36 local unions participating in the program prior to December 1979 were also interviewed. Fourteen favored the program, 3 were neutral or unaware of the program, and 3 had not actually used the program. Major reasons for approval were that use of the program was fairer than layoffs, and workers were generally better off financially because only a portion of earnings were lost and most fringe benefits were maintained. Four union representatives reported initial resistance to the program from their members, but also noted that opposition had lessened once workers became familiar with the program.

These are all only preliminary indications as the data currently available do not permit a definitive assessment of the California program's impact. However, information from other sources can augment what we now know about such programs. The concluding section will deal with comparable programs in Europe. In an appendix, we discuss the results of a hypothetical cost-benefit analysis of short-time compensation.

Short-time compensation in Europe

Programs similar to California's "Work Sharing Unemployment Insurance" have been in effect within the Federal Republic of Germany, Belgium, France, Italy, Great Britain, Luxemburg, Denmark, The Netherlands, Norway, Austria, and most recently on the North American continent in Canada.[15] Of these short-time benefit programs, the German program most closely parallels the framework of the California program (and of those being discussed in the United States). We will concentrate on it.

The German short-time allowance scheme was first delineated in the Placement and Unemployment Insurance Act of July 1927.[16] The law has been revised several times. The most recent amendments were in the Employment Promotion Act of June 1969.

The program is administered by the Federal Labor Institute, an independent organization composed of representatives of labor, business, and the government, which administers unemployment insurance, unemployment assistance, and other labor market measures.[17]

In West Germany, worker eligibility for short-time benefits is determined by eligibility for unemployment insurance. All these programs are financed by a 3-percent payroll tax divided equally between employers and employees up to an earnings ceiling.[18]

The program is available to firms with at least one paid employee. To become eligible, a firm must demonstrate that a reduction in hours of labor is unavoidable, and that work time reductions with short-time benefits will prevent dismissals.[19] Furthermore, employers must document that work-time reductions of 10 percent or more have been made for one-third or more of their employees for a period of four continuous weeks or more.[20] Eligibility has traditionally been denied to firms and industries showing signs of permanent decline.[21]

German law requires that decisions to reduce work time or lay off workers must be agreed to by the employer and the Worker Councils established within most firms.[22] If the Worker Council consents to the program, it is binding upon the affected workers. Dissenting workers can only resign to avoid a shorter workweek.[23]

The German program appears to allow firms considerable discretion in determining what portions of their work forces go on short-time and how use of short-time is adjusted over time. Employers also are allowed to transfer workers within the firm, and some workers may be discharged and others hired so long as most employees retain their jobs.[24]

Once eligibility is determined, the Federal Labor Institute authorizes the payment of specified benefit amounts to workers. The firm pays these benefits directly to its employees, and is reimbursed by the government. As in the California program, the amount of short-time benefits given to claimants is determined by the proportion of full-time unemployment that work-time reductions comprise. The program replaces between 60 and 68 percent of earnings lost because of reduced work time.[25] Short-time benefits have a ceiling but are tax free.[26] However, benefits are reduced by 50 percent of earnings received by recipients for work performed in excess of the reduced work hours provided by the primary employer.[27]

However, available data show that some 90 percent of German recipients do not have their payments limited by the maximum benefit ceiling; and among this large subgroup of participants take-home incomes are almost always maintained at 80 to 90 percent of regular earnings,[28] depending on the extent of work-time reduction.

Firms participating in the program are required to assume the full costs of public health insurance and retirement programs, which, outside the program, are split evenly between employer and employee. However, the government will, on occasion, reimburse firms for up to 50 percent of the cost of health insurance and 75 percent of the cost of retirement programs.[29] In some cases, curtailment of full private fringe benefits which are related to pay levels may occur, but such reductions are typically minor.[30]

The normal maximum duration of benefits is 6 months, but it can be extended for up to as much as 2 years.[31]

While the extent and duration of work-time reductions under the German program varies, a "rule of thumb" generalization is that most beneficiaries had their work time shortened by about 40 percent and that duration has been under 3 months for most participants. Between 1972 and 1977, some 92 percent of beneficiaries suffered a loss of work time of under 50 percent of standard hours, and 57 percent experienced a loss of less than 25 percent. Between June 1977 and June 1978, 56 percent of participating workers received benefits for under 3 months and only 6 percent received benefits for periods lasting longer than 1 year.[32]

Utilization of short-time compensation varies markedly with the business cycle, particularly during the early stages of an economic downturn when firms are not sure whether dismissals and long-term layoffs are necessary. This pattern is empirically dramatized by the rapid upsurge of utilization of short-time compensation at the beginning of the 1975 recession, followed by a decline in use despite the fact that unemployment levels did not fall appreciably. (See table 3.)[33]

Table 3. Annual averages of unemployment and workers under short-time compensation, West Germany, 1968–78

Year	Registered short-time workers	Registered unemployment (number)	Unemployment rate

[1] 1978 figures are preliminary.

NOTE: Unemployment figures are based on the number of registrations at government Employment Service Offices. It is estimated that about 75 percent of the unemployed workers in West Germany register. Unemployment rates are computed on the basis of registered unemployment figures.

SOURCE: *Annual Report for 1976*, Bundesanstalt Fur Arbeit, Republic of West Germany, pages 8 and 65; and *Arbeits-und Sozialstatistik*, Federal Ministry of Labor and Social Affairs, Republic of West Germany, March 1978. Data for 1977 and 1978 cited from Gunther Schmid, "Selective Employment Policy in West Germany: Some Evidence of Its Development and Impact," Discussion Paper Series, International Institute of Management, Berlin, July 1978, page 14.

Ninety-five percent of German workers receiving short-time payments are in manufacturing, mining, and construction. Within these sectors, payment of short-time benefits for shorter working hours is most widely used in all stages of the fabrication of metal products, ranging from the mining of iron and coal to the production of steel, machinery, automobiles, and ships. Electrical products, textiles and construction industries follow in that order.

In contrast to the California program, between one-third and one-half of all workers receiving short-time benefits were employed in large firms with more than 500 workers. Nonetheless, employers with more than 500 employees represented only 5.5 percent of the total number of firms using the program in 1978.

The widespread use of the program in Germany has led observers to conclude that the program has significantly attenuated unemployment. One study has estimated that use of the program reduced full-time unemployment by approximately 175,000 in 1975, and some 52,000 in 1977. (See table 4.)[34] Thus, some observers claim that without the program, full-time unemployment would have been about 16 percent higher in 1975, and about 5 percent higher in 1977.

Despite general agreement that short-time compensation effectively prevents layoffs, the available data leave a number of unanswered questions concerning its job-saving effects. It has been noted that the aggregate work-time reductions have been significantly greater than the estimated reductions of full-time unemployment. (See table 4.) Most analysts suggest that this difference comes primarily from a "silent reserve" (*Stille Reserve*) of employees on reduced work time who do not or cannot claim short-time benefits,[35] but the phenomenon is yet to be fully explained.

Questions and prospects

Despite generally laudatory reports from European representatives of labor, business, and government

Table 4. Estimated impact of short-time compensation on work time and unemployment, West Germany, 1973–77

[Numbers in thousands]

Year	Registered short-time employees	Reduction of full time equivalent work time (employees)	Reduction of full time equivalent unemployment due to short time (employees)
1973	44	16	11
1974	293	106	70
1975	773	272	175
1976	277	90	60
1977	231	77	52
1978[1]	250	84	56

SOURCE: *Mitteilungen aus der Arbeitsmarkt-und Berufsforschung* ("The Development of the Labor Market in the Federal Republic of Germany in 1977"), No. 1, 1977, page 8. (Interpretation of data provided by Beatrice Reubens, Conservation of Human Resources, Columbia University, New York.) Data for 1977 and 1978 cited from Gunther Schmid, "Selective Employment Policy in West Germany: Some Evidence of Its Development and Impact," International Institute of Management, Berlin, Discussion Paper Series, July 1978, page 14.

about short-time programs,[36] a number of reservations have been expressed about the applicability of the concept to the United States. For example, different levels of labor market competition would make the program far less attractive to U.S. firms. Furthermore, European legal restraints on layoffs, particularly those in Germany, are likely to make short-time compensation far more acceptable in Europe. Moreover, large portions of European fringe benefits are administered by the government, thus reducing fixed costs of labor which are likely to deter U.S. firms from participation. Finally, the maximum benefit ceiling for the German program is considerably higher than most American ceilings.[37] This difference is assumed to reduce opposition from senior employees in Germany to a much greater degree than would be likely in the United States.

While there are still many unanswered questions, available information suggests that short-time compensation can do little to help persons who are out of work because they have just entered or re-entered the labor force. Nor is it likely to help those who have already been laid off or voluntarily left their jobs. However, short-time compensation does have potential to prevent full-time job loss among the 3 to 5 million American workers subject to layoffs who comprise about half of the unemployed population.[38]

Despite the potentials of short-time compensation, there are many reservations about its widespread application in the United States. Some union representatives have expressed fear that use of short-time compensation would disrupt hard-won seniority provisions and established union procedures. It has been suggested that layoffs according to seniority are fair and that use of shorter workweeks as an alternative to layoffs would lead to wage losses among higher-paid senior workers. In addition, there is concern that use of the program would stimulate conflicts among workers, leading to a reduction of union solidarity and bargaining power and presenting numerous administrative complications which would effectively prevent certain types of workers from receiving benefits, encourage firms to instigate greater aggregate work-time reductions than would be the case under layoffs, and reduce political pressures for full employment.[39] Yet a 1978 survey of the American labor force indicates that the worksharing unemployment insurance concept is supported by an overwhelming majority of workers.[40]

Some members of the business community have also expressed concern that the program would ultimately be imposed on firms, encourage unions to push for shorter workweeks, and subsidize marginal firms at the expense of healthy ones. While these reservations are not unanimously expressed by all sectors and levels of labor and business,[41] they do represent important issues which must be dealt with prior to widespread acceptance of short-time compensation as a major social policy.

The future of short-time compensation within the United States will be determined ultimately by discussions among advocates and opponents, research and policy evaluation,[42] and perhaps further experimentation and trial runs. ☐

[11] For example, if a recipient was eligible for a total of $3,120 in UI benefits (which is the maximum 1980 weekly benefit of $120 for 26 weeks), and received a total of $480 or $24 a week in worksharing benefits for 20 weeks, he or she would have $2,640 ($120 a week for 22 weeks) worth of regular UI if laid off after using the shared work program.

[12] If individual annual incomes are over $10,000 or joint spouse annual incomes are over $25,000, unemployment insurance benefits are taxable under Federal law.

[13] In remarks to the National Commission on Unemployment Compensation in New York, New York on Aug. 24, 1979, John L. Zalusky, an economist with the AFL-CIO Department of Research, argued that the worksharing program may be used selectively so that lower-skilled and junior employees are laid off with the program being used to retain higher skilled or senior workers, thus defeating much of the affirmative action goals of the program.

[42] For example, the California "Work Sharing Unemployment Insurance" is now under an intensive 2-year evaluation sponsored by the California Employment Development Department and the U.S. Department of Labor. The final analysis will be issued before that date. Such research, ongoing dialogue, and possible experimental programs in other States should shed light on the applicability of short-time compensation in the United States.

APPENDIX: Economic Costs and Benefits

The economic costs and benefits of short-time compensation must be determined by empirical evaluation of working programs. However, data on the costs of labor and social programs can be used to illustrate likely economic impacts of using short-time compensation instead of layoffs. This can be accomplished by a hypothetical example developed to contrast laying off 20 percent of low seniority and low income employees with a 20 percent (1 day) work-time reduction with short-time benefits within a fictitious firm employing 100 wage earning workers. These workers, are postulated to have average 1980 U.S. pay levels and benefits under the income tax and unemployment insurance benefit conditions existing in California. Further, the income and fringe benefits are distributed within this fictitious group of workers roughly to reflect prevailing U.S. conditions. Thus, the highest paid 20 percent receives a gross weekly wage of $380, the average worker gross weekly earnings of $265, and the lowest 20 percent a gross weekly income of $155. The lowest paid 20 percent are assumed to have low seniority and be subject to layoffs when they occur. The estimated economic impacts of short-time compensation and layoffs under these conditions are shown in appendix table 1.

The use of short-time compensation as opposed to layoffs will produce economic gains for junior workers at the expense of those with seniority, minimize losses to all parties due to reduced income taxes and short-time benefits, and improve the aggregate economic well-being of the total work group with a 4-day workweek. For example, high seniority workers (top fifth earning level) would take home net weekly paycheck of $268.48 or about 91 percent of the $294.94 they would receive under full-time work conditions. Low-seniority employees (lowest earning levels) would take home $128.16 under short-time compensation, in comparison to the $74 in unemployment insurance benefits they would receive if totally laid off. The average worker would maintain about 92 percent of his or her regular take home earnings under short-time.

Under short-time compensation, all workers would maintain some degree of job attachment, as well as all or most of the fringe benefits which accompany employment. When the value of these benefits is added to net pay, the average employee under short-time compensation would maintain 94.2 percent of total full-time "take home" compensation as opposed to 92.5 percent under layoffs. Additionally, all workers experiencing reduced workweeks would have an additional day off and higher effective per hour pay rates due to the partial income subsidy. Finally, because approximately one-fifth of unemployment insurance applications are judged ineligible due to inadequate base earnings,[1] low seniority workers without eligibility would maintain at least partial wages as opposed to complete loss of income resulting from total layoff.

Although firms will spend more per hour of labor on fixed fringe benefit commitments, overall labor costs are likely to be lower under the program because reductions in work time for all employees will tend to reduce average weekly wages. The average sum of wage and benefit costs per hour in this example is $9.81 under the program as opposed to $10.22 under regular layoffs and $9.26 under standard full-time conditions. Lower turnover costs resulting from avoidance of recall, new hiring, and training would likely lead to further savings by firms. These savings are likely to be at least partly counterbalanced by a slight increase of unemployment compensation taxes on the firm as a result of higher partial unemployment insurance payment given to senior workers with large base earnings. Of course, hourly labor costs can be expected to be higher under both short-time compensation and layoffs than they would be under full-time conditions, suggesting that firms would not wish to utilize the program unless confronted with economic problems.

Presumed benefits to workers and firms resulting from use of short-time compensation may be gained

Appendix table 1. Hypothetical[1] comparison of costs and benefits of short-time compensation and layoffs to the firm, workers, and government

[Typical firm=100 production workers over one week]

[1] The assumptions underlying the table are: (1) 40-hour workweek with no overtime, (2) all employees eligible for unemployment insurance, (3) lowest paid 20 percent of workers are also lowest seniority and subject to layoffs, (4) distribution and levels of wages and benefits approximate late 1979 conditions for nonsalaried U.S. production workers, and (5) taxes and unemployment insurance benefits based on California conditions.

[2] Gross average weekly wage approximated from August 1979 average U.S. manufacturing workers' weekly income (*Monthly Labor Review*, October 1979, page 96), and typical distribution of earnings within a work group of 100 employees into highest 20 percent and lowest 20 percent approximated from national income distribution patterns for male wage earners in manufacturing industries (*Current Population Reports, Consumer Income*, Series P. 60, No. 118, March 1979, pp. 228–29).

[3] Dollar amount of taxes deducted from gross weekly earnings to determine net earnings based on Federal and California income tax withholding rates for a worker with three exemptions (California Employment Development Department, January 1979), and 1979 Social Security tax rates requiring payment of 6.13 percent of the first $22,900 of individual annual earnings by both employer and employee.

[4] Dollar cost of fringe benefits such as medical care, private retirement pensions and paid time off computed as 32 percent of gross earnings based on available data (*Handbook of Labor Statistics 1977*, page 237) and *Employment Benefits* (U.S. Chamber of Commerce, 1975).

[5] Full weekly unemployment insurance benefits and 20 percent benefits based on California benefit determination formula in effect in January 1980. Full unemployment insurance benefits would be $74 a week for a fully unemployed worker earning $165 a week, $107 for a worker earning $265 a week, and $120 for a worker earning $380 a week or more. The California unemployment insurance benefit ceiling is $120 a week.

[6] Unemployment insurance tax payments computed from estimated typical employer unemployment insurance tax based on average 1977 California tax rate of 2.46 percent (*Actuarial Report of the California Unemployment Fund*, 1977, pp. 28–29) adjusted upward 4 percent to account for employee turnover (*Employment and Training Report of the President*, 1979, p. 332) and prorated over one-year period to represent average unemployment tax expenditures by employer on first $6,000 of employee earnings for varied levels of continuously earned annual income.

[7] Because of the unavailability of acceptable data showing dollar amounts of employer turnover costs resulting from hiring and training, and public program expenditures associated with varied levels and types of work losses, it was necessary to note expected impacts in terms of (↑) for increased expenditures, (—) for no change in expenditures, and (↓) for reduced expenditures.

through increased costs to the Nation. For instance, if the duration of unemployment is presumed to be equivalent, the level of average benefits is likely to be higher than unemployment insurance payments because benefits for senior workers with higher earnings will be greater than those collected by low-paid junior workers. Such extra costs are likely to be partially recouped over the long run by increased unemployment insurance taxes for firms participating in the program. Use of short-time compensation will also reduce general tax revenues received by the government. Because workers, particularly those with higher incomes, will pay proportionally less income taxes with reduced earnings, total revenues from income taxes will be lower. Specifically, the weekly State, Federal and social security taxes collected from the average program participant in our hypothetical example would be $59.88, as opposed to $46.80 for the same worker experiencing layoffs. To some degree, these losses will be slightly offset by lower expenditures on public programs such as food stamps, social security and medicare for work groups using short-time compensation as opposed to layoffs.[2]

Probing the issues of unemployment duration

Data ambiguity and measurement problems have created controversy in interpreting unemployment duration; after a careful review of the issues, most jobless spells appear short but persistent unemployment is important; recession extends duration for all

NORMAN BOWERS

If most persons experiencing unemployment remain jobless for only a short period, is the labor market so active that the unemployed easily find their usual kind of work? And, as a corollary, that chronic and persistent joblessness is unimportant? Or do such data merely reflect the frequent movement away for unstable and marginal jobs that are considered unsuitable?

Whatever one's belief concerning the efficacy of different theories of unemployment and the labor market, accurate measures of various dimensions of the incidence and duration of unemployment are important. The purpose of this article is to discuss some methodological, measurement, and interpretative issues surrounding existing statistics on unemployment duration. The primary data source for this analysis is the Current Population Survey (CPS).

Consistent with past research, a large number of spells of unemployment were found to be typically of short duration, although obvious cyclical patterns also were found. The implications for understanding how the labor market functions depend critically upon both the outcome of a spell of joblessness and the extent of multiple periods of unemployment per worker over time. Based on this analysis, unemployment appears to be concentrated among a relatively small group of workers who are unemployed for a rather extensive length of time. In addition, there appears to be a pronounced cyclical pattern to the concentration of unemployment, as long-term joblessness rises extensively in recessions. However, the data alone do not verify or refute any of the existing theories of labor market behavior.

Some methodological issues

For many analysts and policymakers the length of a spell of unemployment—whether 4 or 40 weeks—is viewed as an index of economic welfare. Thus, the plight of the long-term unemployed and the impact of economic downturns on duration are often discussed. However, the seemingly simple question—how long does an unemployed person remain unemployed?—is not easily answered on the basis of regularly published data from the CPS (or most other labor force surveys, for that matter). To understand this, a brief overview of the CPS is necessary.

The CPS is a monthly survey of a rotating group of approximately 65,000 households (strictly speaking, addresses). Each month, Census Bureau enumerators visit the households in the sample and ask a series of structured questions about the labor force status of each member 16 years of age and over during the preceding or reference week. Persons without a job but looking for work are asked how long they have been looking for work. Thus, what the CPS measures is the length of a spell that is still in progress, which is conceptually distinct from the length of a *completed* spell of

---

Norman Bowers is an economist in the Office of Current Employment Analysis, Bureau of Labor Statistics.

unemployment. Published data measure a cross-section of the unemployed prior to the completion of their spells. The difference between an in-progress and a completed spell of unemployment is analogous to the difference between the average life span (the average of a completed life) and the mean age of the population (the average of lives currently in progress). In addition, some unemployment spells are not measured in the survey—those that occur between survey dates.

Before discussing the implications of this distinction, it might be fruitful to examine the distribution of unemployment by duration of spells in progress during 1968–79. Table 1 shows that, on average, about 6 million people were unemployed in 1979, and approximately 1.2 million were unemployed for more than 15 weeks. The average duration of these "in-progress" spells was 10.8 weeks. In general, average duration varies directly with the unemployment rate, as can be seen by simply contrasting 1969 with the recession year of 1975. As should be clear from the previous discussion, however, table 1 cannot be used as an estimate of, say, the number of completed long-term (15 weeks or more) spells of unemployment in a year. This is so for two reasons: first, many of the jobless remain among the long-term unemployed from month to month and are counted repeatedly; second, some of the unemployed reporting less than, say, 5 weeks will eventually experience more than 15 weeks of unemployment. At the same time, spells of unemployment that occur entirely between survey dates are missed.[1]

This suggests that there are two different measurement problems in using the data on spells in progress to estimate the length of completed spells. These phenomena will be labeled "interruption" and "length" bias, following Salant and others.[2] As noted earlier, the spells "captured" by the CPS are only part-way to their completion at the time of the survey—that is, they are "interrupted" spells. Thus, the average duration of spells in progress may underestimate the length of a completed spell. However, there is also a bias in the opposite direction. Longer spells have a better chance of being measured in the survey and so tend to make the measured average duration greater than the average duration of a completed spell—length bias.

Which of these effects will predominate depends on what is called the "escape rate" or the probability that a person's unemployment will end in "N" weeks provided that it has not ended before that time. Salant has shown that the relationship between the expected length of interrupted and completed spells can be deduced from a knowledge of "escape rates."[3] This technique is applied to CPS data in the next section; however, a brief discussion of escape probabilities derived from CPS data is necessary.

Past research using CPS data has shown that, in the aggregate, the likelihood of escaping unemployment declines with length of time unemployed. In other words, the probability of remaining unemployed increases with the length of unemployment already experienced.[4] It must be emphasized that this relationship is based on aggregate data and does not necessarily mean that individuals have declining propensities to escape unemployment. For example, individuals or homogenous groups of the unemployed could have constant but different escape rates over time, but as the duration of unemployment increases the unemployed will be disproportionately composed of those with low escape rates. On the other hand, there may, in fact, be a causal relationship between duration and escape, such that the longer a person is unemployed the less chance she or he has of reemployment.[5]

Methods to estimate the expected duration of a completed spell of unemployment, using supplementary data from the CPS, are described in the next section.

Table 1. Distribution of the unemployed by duration of in-progress spells of unemployment, 1968–79

[In thousands]

Year	Total unemployed	Number of weeks unemployed					Average duration (in weeks)	Unemployment rate
		Less than 5	5–10	11–14	15–26	More than 26		
1968 . . .	2,817	1,594	613	197	256	156	8.5	3.6
1969 . . .	2,831	1,629	827	200	242	133	8.0	3.5
1970 . . .	4,088	2,137	958	331	427	235	8.8	4.9
1971 . . .	4,993	2,234	1,143	435	665	517	11.4	5.9
1972 . . .	4,840	2,223	1,089	369	597	562	12.1	5.6
1973 . . .	4,304	2,196	966	330	475	337	10.0	4.9
1974 . . .	5,076	2,567	1,153	418	563	373	9.7	5.6
1975 . . .	7,830	2,894	1,738	714	1,290	1,193	14.1	8.5
1976 . . .	7,288	2,790	1,594	625	1,003	1,336	15.8	7.7
1977 . . .	6,855	2,856	1,507	582	898	1,012	14.3	7.0
1978 . . .	6,047	2,793	1,377	499	746	633	11.9	6.0
1979 . . .	5,963	2,869	1,366	496	684	516	10.8	5.8

Gross change data

Any longitudinal survey opens up the possibility of examining the movement of individuals from one labor force status to another—for example, from unemployed to employed. As noted previously, the CPS is a monthly survey of a rotating group of households. The CPS comprises eight independent panels or rotation groups. Each household is interviewed in each of 4 consecutive months, dropped from the sample for 8 months, and reinterviewed for 4 final months. Therefore, potentially three-fourths of the sample are common from month to month.[6]

Because of this overlap, it is possible to match a person's labor force status for the current and previous months and measure the number of people who remain employed, unemployed, or not in the labor force, or who move between each of these states. Although a variety of detailed information is available from the gross change data, here it is only necessary to concentrate on the nine possible labor force flows among the employed (E), unemployed (U), and not in the labor force (N), as represented in the following tabulation:

Labor force status in previous month	*Labor force status in current month*		
	E(t)	*U(t)*	*N(t)*
$E_{(t-1)}$	EE	EU	EN
$U_{(t-1)}$	UE	UU	UN
$N_{(t-1)}$	NE	NU	NN

The meaning of the flows is as follows: EE represents the number of workers who were employed for the 2 successive months, EU is the number who were employed the previous month (t−1) who became unemployed in the next month (t), and so forth. The probability of making a labor force status transition is simply the number of people who made any given change divided by the number in the original state. For example, the probability that an unemployed worker will remain unemployed is UU/U_{t-1}. Each probability is called a transition rate. Before estimating duration from the actual statistics, it is important to note some of the limitations of the data (for references, see footnote 6).

The accuracy of the gross change data has been questioned in part because they normally do not agree with the labor force status counts from the full CPS. For example, the change in unemployment in any 2 months can be calculated two ways: first, by subtracting the gross flows out of unemployment (UE + UN) from the flows into unemployment (EU + NU); or, second, by subtracting the number unemployed in the current month from the number unemployed in the previous month. The results are usually different in magnitude and, sometimes, in direction because the samples and estimating methods used differ significantly.

It is generally acknowledged that there are three types of errors in the gross change data.[7] First, and least important, is sampling variability; that is, the problem of estimating labor force status from less than a complete census. This is a problem of all sample surveys, but is likely to be more important for the gross change data because individuals must be surveyed 2 consecutive months. Therefore, movers, nonrespondents, and the first and fifth rotation groups are excluded from the gross change data, which are actually based on only about two-thirds of the full sample. This reduction in the sample may serve to bias the results, as some evidence exists that persons excluded have a more marginal labor force attachment than those who are matched.[8]

The second source of error is the result of misclassification of labor force status. Some evidence of the severity of misclassification is available from the CPS reinterview program.[9] Each month a sample from the CPS is selected for reinterview as a quality check. The reinterviews take place 1 week after the initial survey and use the regular CPS questionnaire. The results of the reinterview program suggest that, because of offsetting errors, net changes in labor force status are only moderately affected by misclassification. Despite this cancellation of errors in the published data, a substantial amount of apparently spurious volatility is present in gross changes. It should also be noted, however, that the CPS reinterview uses more experienced enumerators which may introduce measured changes between the original and reinterview surveys that would not exist between the original and subsequent surveys. Thus, the reinterview program may not give an exact measure of spurious movement in the gross change data. Whatever the cause of the misclassification, the effect on the gross change data is to magnify the flows between labor force categories.[10] It should be emphasized that the vast majority of people are classified correctly: the point, however, is that errors that cancel each other in the full CPS are cumulative in the gross change data. The extent of, or direction of, bias to estimates of the duration of a completed spell of unemployment is uncertain, though some researchers have argued that, in the absence of the errors, duration measures would be much higher because the correct measure of changes in labor force status would be lower.[11]

The third source of error, which is seemingly inherent in any panel surveys, is "rotation group bias": respondents are conditioned by the process of reinterview.[12] That is, responses to the survey questions change simply as a result of length of time in the survey. In addition, the probability of being reinterviewed in, say, 2 consecutive months is different among various labor force and demographic groups. The probability of reinterview can be affected by a variety of reasons, such as changing place of residence and refusing to be reinterviewed. The evidence we have on rotation group bias suggests that the movement between unemployment and not in the labor force is most affected by these problems.[13]

Despite these problems, the gross change data do provide a wealth of useful information on the U.S. labor force: in particular, the data can be used to estimate the duration of completed spells of unemployment.[14]

Estimating duration of unemployment. Estimating the expected duration of unemployment, E(D), from the gross change data is straightforward. Recall that a person unemployed in one month can, in the subsequent month, remain unemployed (UU), become employed (UE), or drop out of the labor force (UN). The expected duration of unemployment is dependent upon the probability of escaping or leaving unemployment, which is the sum of the probability of withdrawing from the labor force or becoming employed. Formally, expected duration is

$$E(D) = \frac{1}{ESC}$$

where ESC is the probability of escape from unemployment from month-to-month. To impute expected duration from a given escape probability it is necessary to assume that individuals have a constant escape rate while unemployed. That is, an individual's escape probability is independent of duration of joblessness.[15] This assumption is critical because otherwise the expected duration of a completed spell is also dependent upon the current length of unemployment experienced, and the calculations become very complicated.

Table 2 contains information on the probability of leaving or continuing unemployment for selected years. Taking 1969 as an example, if on average 100 people were unemployed in month t−1, then 35 of those people were employed, 29 withdrew from the labor force, and 36 remained unemployed in the following month. The fourth column of table 2 shows the estimate of the expected duration of a spell of unemployment. These estimates are presented as "weeks of unemployment." This was done by multiplying expected duration, E(D), from the above equation, which is based on monthly probabilities of labor force movement, by 4.3—the average number of weeks in a month (thus, $E(D) = 1/ESC \times 4.3$). The final column in table 2 shows the expected duration of unemployment for a "persistent jobseeker." This is a measure of unemployment duration conditional upon not withdrawing from the labor force (UN); rather, the "persistent jobseeker" searches until he or she finds a job (UE). The implications of these data will be discussed in detail later, but for now it should be noted that the expected duration of the persistent jobseeker is the probability of moving from unemployed to employed plus the probability of remaining unemployed divided by the probability of moving from unemployed to employed, all multiplied by 4.3 weeks.

Table 2. Probability of leaving or continuing unemployment, by duration of unemployment, annual averages, selected years, 1969–79

Year and current duration	Probability of moving from unemployment to—		Probability of continuing unemployment	Expected duration of a completed spell of unemployment (in weeks)	
	Employment	Not in labor force		All workers	Persistent jobseekers
1969					
Total	.3516	.2910	.3570	6.7	8.7
Less than 5 weeks	.4019	.2999	.2982		
5 to 10 weeks	.3069	.2916	.4015		
11 to 14 weeks	.3143	.2571	.4286		
15 to 26 weeks	.2390	.2550	.5060		
More than 26 weeks	.2158	.2950	.4892		
1971					
Total	.2770	.2409	.4821	8.3	11.8
Less than 5 weeks	.3368	.2788	.3844		
5 to 10 weeks	.2667	.2409	.4924		
11 to 14 weeks	.2488	.2019	.5493		
15 to 26 weeks	.2043	.1659	.6298		
More than 26 weeks	.1591	.2004	.6405		
1975					
Total	.2338	.2028	.5634	9.8	14.7
Less than 5 weeks	.3083	.2531	.4386		
5 to 10 weeks	.2381	.1987	.5632		
11 to 14 weeks	.2139	.1761	.6100		
15 to 26 weeks	.1734	.1437	.6829		
More than 26 weeks	.1234	.1669	.7101		
1978					
Total	.2855	.2319	.4826	8.3	11.6
Less than 5 weeks	.3418	.2604	.3978		
5 to 10 weeks	.2694	.2246	.5060		
11 to 14 weeks	.2336	.2008	.5656		
15 to 26 weeks	.2227	.1743	.6030		
More than 26 weeks	.1831	.2091	.6078		
1979					
Total	.2906	.2283	.4813	8.3	11.4
Less than 5 weeks	.3450	.2560	.3990		
5 to 10 weeks	.2835	.2132	.5033		
11 to 14 weeks	.2422	.1942	.5636		
15 to 26 weeks	.2169	.1837	.5994		
More than 26 weeks	.1514	.2072	.6414		

There are a number of interesting features in table 2. First, in each year the probability of remaining unemployed increases as current duration increases. This may result from the "sorting" effect, or there may be a causal relation between an individual's likelihood of exiting unemployment the longer he or she is out of work. Again, to estimate the expected duration it is necessary to assume that the sorting effect is true. Second, there is a strong cyclical pattern to the data. The jobless in the recession year of 1975 had a much higher chance of remaining unemployed and a much lower chance of going from unemployed to employed.

The formula for expected duration results in estimates for completed durations ranging from a low of 6.7 weeks in 1969 to 9.8 weeks in 1975 (column 4 in table 2). This compares to the average duration of an in-progress spell of 8 weeks in 1969, and 14.1 weeks in 1975 (table 1). This result indicates that the length bias dominates the interruption bias in the published statistics.[16]

The data on the transition probabilities also permit the estimation of the number of completed spells of unemployment within any given period, both overall and within each transition field. There are at least two sources of bias to this estimate. First, it is important to note that the estimate will be a lower bound of the actual number of spells because several short spells may occur between the survey dates and, therefore, will be missed. Second, as a result of errors in the gross change data, it is likely that the true transition probabilities are lower than the measured probabilities: thus, the true number of unemployment spells will be lower than the estimates presented here. These two problems have opposite effects on the estimates. However, it would be exceedingly difficult to measure the actual magnitude of the bias introduced because of these problems.

Both tables 1 and 2 are necessary to estimate the number of spells of unemployment in a year. Table 1 shows, for example, that in an average month in 1969, 1.6 million people had been unemployed for less than 5 weeks. From table 2, it is possible to calculate the probability that a person unemployed less than 5 weeks will exit unemployment by the next survey month. The number of completed spells in any given transition field is calculated as follows:

$$\text{Spells} = \text{Number of in-progress spells} \times \text{Probability of escape} \times 12$$

Table 3 contains the results of this exercise. Thus, in 1969, there were an estimated 22 million spells of unemployment, and 14 million of these spells were less than 5 weeks. In 1975, on the other hand, there were 42 million spells; compared to 1969, there were proportionately more long-term spells in 1975, which is exactly what one would expect in a cyclical downturn.

Of course, the estimates in table 3 pertain to spells of unemployment. The estimated 37 million spells in 1979, for example, include a number of individuals who experienced more than one spell of joblessness over the year. This is particularly true of those completed spells of relative short duration. However, because of their length, the 2.2 million spells of 27 weeks or longer may correspond roughly to the number of people who were out of work that long in one spell (but not those who experienced a total of more than 26 weeks of unemployment over the course of the year).

In summary, the measurement of the length of a completed spell of unemployment is conceptually simple; but, the empirical difficulties are important enough that the estimates should be taken as rough guides only. The fact that these estimates are generally comparable to those obtained in research utilizing different methods increases the confidence in the estimates. Given these caveats, the comparison of tables 1 and 3 suggests some interesting interpretations of the structure of unemployment. On average, the estimated duration of a completed spell is just about 75 percent of the duration of the (measured) in-progress spell. And, while there are important cyclical patterns, a large number of spells are typically of very short duration.

Table 3. Estimated completed spells of unemployment, by duration of unemployment, 1968–79

[In thousands]

Year	Total spells	Number of weeks unemployed					Expected duration of a completed spell (in weeks)
		Less than 5	5–10	11–14	15–26	More than 26	
1968	21,587	12,372	4,474	1,272	1,519	964	6.8
1969	21,841	13,718	4,503	1,371	1,434	815	6.7
1970	27,323	16,445	5,933	1,711	2,075	1,159	7.7
1971	31,002	16,503	6,962	2,353	2,945	2,230	8.3
1972	31,023	16,755	6,729	2,024	2,981	2,534	8.0
1973	29,661	17,018	6,267	1,895	2,520	1,961	7.5
1974	32,854	19,330	7,092	2,017	2,677	1,738	8.0
1975	41,012	19,496	9,110	3,341	4,909	4,156	9.8
1976	39,613	18,926	8,527	2,760	4,193	5,207	9.5
1977	39,878	19,874	9,091	2,774	3,998	4,141	8.9
1978	37,480	20,183	8,163	2,601	3,554	2,979	8.3
1979	37,126	20,691	8,321	2,597	3,288	2,229	8.3

Interpreting duration data

As noted at the outset of this article, the meaning of the apparently short durations estimated in table 3 is fraught with difficulties. For example, one economist has asserted that the data support the notion of "an active labor market in which almost everyone who is out of work can find his usual type of job in a relatively short time."[17] Another perspective contends that the data indicate that, while many workers pass through the state of unemployment, chronic and persistent joblessness is unimportant.[18] Another group of theorists, ranging from those who argue that the labor market is divided into segments between which mobility is constrained to those who utilize labor turnover models, has argued that duration statistics are simply inadequate as any measure of economic welfare: rather, short spells of measured unemployment could be the result of frequent movement from jobs that are unstable, menial, or otherwise unpreferred.[19] Finally, it must be emphasized that the gross change statistics do not provide a complete picture of the labor market. In particular, a large proportion of job changes occur without any intervening period of unemployment. Thus, sole reliance on the gross change data may lead one to exaggerate the overall importance of labor force flows.

The effects of labor force withdrawal. As the preceding discussion indicates, one important issue in interpreting duration statistics concerns the outcome of a spell of unemployment. Measured short durations may not imply much about the ease of finding one's "usual line of work" if individuals escape unemployment by withdrawing from the labor force or, perhaps, by adjusting to poor labor market conditions and taking a temporary job while waiting for job prospects to improve.[20] As an example of the magnitude of labor force exit, it has recently been estimated that 45 to 50 percent of all unemployment spells end by withdrawal from the labor force.[21]

Some additional information about the impact of labor force withdrawal on duration is contained in the last column of table 2. Here, the expected duration of unemployment for those who do not withdraw from the labor force has been calculated. The expected duration of the persistent jobseeker is substantially higher than the conventional calculation which includes the effect of labor force withdrawal: in 1969, 8.7 versus 6.7 weeks; in 1975, 14.7 versus 9.8 weeks; and, in 1979, 10.8 versus

8.3 weeks. It is crucial to note that this calculation is simply illustrative and is not based on the actual experience of people who do not leave unemployment until they find a job. The calculation assumes that those persons who end their unemployment by dropping out of the labor force would have had the same likelihood of finding a job if they had continued to search as those who actually did continue to search. Moreover, it is precisely those groups that are most marginally attached to the labor force—for example, school age youth—who tend to experience frequent spells of short-term joblessness. Nevertheless, the data do underscore the necessity to exercise caution in the interpretation of unemployment duration statistics.

Some perspective on the meaning of labor force exit can be gained by looking at the patterns of labor force transitions. Table 4 contains this information for selected years. The flows have been calculated as probabilities.

The probabilities of moving from employment or unemployment to not in the labor force can provide some (limited) information on the interpretation of labor force withdrawal. That is, if withdrawal is truly voluntary—given real life ambiguities—then, even if exits are large in magnitude, they might, nevertheless, be of little concern for understanding the labor market.

The question of interest: to what extent do people drop out of the labor force because they choose not to work rather than because they become discouraged about the prospects of finding a job? This is a very difficult question to answer precisely on the basis of existing data. However, George Perry has suggested that if all labor force leaving is truly voluntary, then one might expect that the employed and unemployed would be equally as likely to drop out of the labor force.[22] Here, the rate of withdrawal from employment might be thought to represent a "normal" rate of withdrawal resulting from things like home responsibilities. This might be considered a rough measure of purely voluntary withdrawal.

As table 4 shows, in each of the years presented, the rate of withdrawal from unemployment swamps the withdrawal rate from employment. On average, in 1969 only 4 percent of the employed withdrew while 29 percent of the unemployed withdrew. Although these exit rates differ by demographic groups, the data strongly suggest that only some small proportion of labor force exit from unemployment is strictly voluntary in the sense of not depending on the prospects of finding an acceptable job. This, admittedly rough, evidence has received substantial support from other research as well.[23]

However, before too much reliance is placed on the suggestion that labor market discouragement is the primary cause of withdrawal from the labor force following unemployment, other evidence needs to be examined. BLS currently compiles quarterly data on discouraged workers—persons who want a job but who are not looking for work because they believe they could not find it. The average number of discouraged workers was 574,000 in 1969; 1,082,000 in 1975; 1,010,000 in 1977; and 750,000 in 1979. The interesting question, however, is not how many workers become discouraged but, rather, what proportion of the people who leave unemployment to move outside the labor force subsequently are classified as discouraged workers? The one piece of evidence that is available on this question is based on the research of Kim Clark and Lawrence Summers. (See footnote 11.) They calculated that, in 1977, just 15 percent of the outflow from unemployment became classified as discouraged workers. However, fully 46 percent of this group said they wanted a job now.[24] Exactly where the truth lies in assessing whether labor force withdrawal is really "voluntary" or "involuntary" cannot be pinpointed solely on the basis of scanning a wide array of data; adequate answers will only be forthcoming with the development of robust explanatory theories of labor market dynamics.[25]

Table 4. Probability of moving from one labor-market state to another in different business cycle conditions, 1969, 1975, and 1978

Labor force flow from—	1969	1975	1978
Employment to unemployment	0.0100	0.0191	0.0145
Employment to not in labor force	.0434	.0351	.0340
Unemployment to employment	.3516	.2336	.2855
Unemployment to not in labor force	.2910	.2028	.2319
Not in labor force to employment	.0507	.0445	.0492
Not in labor force to unemployment	.0162	.0271	.0251
Average unemployment rate	3.5	8.5	6.0

Ambiguity of labor force classification. The unemployed/not in the labor force distinction has recently been criticized for being too ambiguous and arbitrary. Clark and Summers, in particular, have argued that the flow between unemployment and not in the labor force in table 4 might be primarily the result of the misclassification of consistent behavior.[26] They cite evidence—discussed earlier in this article—on the existence of rotation group bias and other classification problems. Because Clark and Summers see the crucial concept of "looking for work" as too ambiguous, particularly in light of evidence they have presented on the relative brevity of labor force withdrawal, they conclude that

> "It appears that many of those who withdraw experience a brief spell outside the labor force and a further period of "reentrant" unemployment. The official statistics capture two relatively brief spells of unemployment, yet the evidence presented here suggests that the experience might be more appropriately characterized as a single lengthy spell of unemployment."[27]

Undoubtedly, for some people at least, the distinction between being unemployed and not in the labor force is unclear. However, the phenomenon of temporary labor force withdrawal is not well understood theoretically. Further examination of this issue is certainly desirable.

One thing stands out from this discussion on labor force exit: irrespective of one's view as to how labor force flows should be interpreted, accounting for the flows is necessary to render the meaning/significance of duration statistics intelligible.

The meaning of unemployment duration might be sharpened by considering the unemployment experience over a period longer than the "average" month and by analyzing the concentration of unemployment.

Multiple spells of unemployment and the concentration of total unemployment. The length of time an individual spends unemployed is the product of both the average duration of an unemployment spell and the number of separate spells. In an economy where repeated spells of unemployment are not unusual, the short average duration of completed spells of unemployment may understate the impact of joblessness on individuals.[28] First, many people may suffer multiple spells of unemployment, so that average duration understates their total unemployment experience. Second, persons experiencing only one spell may have more unemployment than suggested by the data on average duration of a completed spell, because single spells tend to be longer than the average of multiple spells.

Data on the prevalence and average duration of unemployment spells are available from the "Work Experience" supplement to the CPS. But these data have important limitations.

Every March, a series of questions about the previous year's labor force experience is asked of respondents in the Current Population Survey. Included are questions on the total length of time the respondent was unemployed and on the number of spells of unemployment experienced. The major potential biases of the data result from recall problems and interruption bias. In addition, the work experience questions do not appear well suited to measure jobseeking activity associated with labor force entry. Recall problems are straightforward: people may have trouble accurately remembering what they were actually doing, say, 8 months ago; in particular, individuals may not recall a brief period in which they were unavailable for work and, therefore, report one longer spell of unemployment.[29] The evidence suggests that the data for prime working age males are consistent with the monthly CPS, but that women and teenagers tend to report fewer weeks of unemployment than implied in the monthly figures. Interruption bias concerns the fact that the period of observation is 1 year, so that some spells of unemployment will be interrupted by both the beginning and ending of the year. This means that even work experience data do not translate into completed spells of unemployment.

Table 5. Average duration of unemployment by spells of unemployment, for all persons with some work experience, 1967–78

Year	Total duration of unemployment (in weeks) for people with:			Average spell length (in weeks) for people with:			Total number of spells (in thousands)[2]	Percent unemployed with more than one spell
	1 spell	2 spells	3 spells or more[1]	1 spell	2 spells	3 spells or more[1]		
1967	7.6	13.3	16.5	7.6	6.7	4.7	16,449	31.6
1968	7.2	13.3	16.5	7.2	6.7	4.7	15,681	31.0
1969	7.5	12.4	16.5	7.5	6.2	4.7	16,719	32.2
1970	10.0	15.4	19.1	10.0	7.7	5.5	20,489	33.6
1971	11.8	17.6	20.4	11.8	8.8	5.8	21,515	32.5
1972	11.2	16.4	19.4	11.2	8.2	5.5	20,855	32.6
1973	9.7	15.2	18.3	9.7	7.6	5.2	20,325	32.4
1974	9.8	15.7	18.0	9.8	7.9	5.1	25,569	36.0
1975	14.4	19.2	19.4	14.4	9.6	5.6	27,422	31.3
1976	13.8	18.4	20.3	13.8	9.2	5.8	27,405	32.7
1977	12.9	17.1	18.8	12.9	8.6	5.4	26,399	32.6
1978	12.0	16.1	18.1	12.0	8.1	5.2	24,400	32.5

[1] Assumes average of 3.5 spells.

[2] Excludes persons who looked for work but did not work.

Table 5 contains information on the total duration and average duration by number of reported spells. The last two columns of table 5 show the total number of spells reported and the percent of those who experienced more than one spell of unemployment. The average durations in table 5 are based on the number of persons reporting both some work experience and unemployment. It excludes all persons who looked for work but did not work at all because there is no information on the number of spells of unemployment. The average duration of unemployment was taken as the midpoint of the following intervals: 0–5; 6–10; 11–14; 15–26; and 27–52. This is a simple assumption, but it should not affect the relative values of the estimates because it is used consistently.

The data are suggestive of several phenomena. First, as expected in a retrospective framework, the total number of spells reported is less than the estimated number of spells from table 3. Second, repeat spells seem to be frequent enough that they cannot be ignored when considering the overall experience of unemployment. For example, in 1978, more than 30 percent of all persons with some unemployment reported more than one spell. Many persons with multiple spells of unemployment work in industries that are highly seasonal or cyclical, or both. The construction industry is one of the best examples; whereas in 1978 construction workers made up only about 6 percent of those with work experience, about one-fifth of all persons with 3 or more spells in 1978 were in the construction industry. Production workers in the automobile industry often experience multiple spells of unemployment because of effects of both model changeover and economic downturns. Not all persons who experience multiple spells can be neatly classified into a particular industrial situation, however. There is some evidence that some people are frequently unemployed because they leave jobs to escape from menial tasks and end up moving form one unsatisfactory job to another, often experiencing a spell of unemployment or exiting the labor force for a brief period.

Another important feature of table 5 is that the average duration of unemployment consistently decreases with the number of spells experienced. That is, while the total amount (in weeks) of unemployment increases as number of spells increase, it does so less than proportionately. Similar patterns of diminishing duration for additional unemployment spells have also been found from direct observations of individuals.[30]

Table 5 indicates that the estimated average duration of unemployment is dependent upon the number of spells the average unemployed person will experience. Statistics on the estimated duration of a completed spell of unemployment are underestimates of the total experience of unemployment: persons with a single spell suffer longer average durations than those with multiple spells; those with multiple spells experience more total unemployment than the average because of the multiplicity of their spells.[31]

The concentration of unemployment. The picture presented thus far has focused on the average duration of unemployment and the number of unemployment spells. It is incomplete: the differential impact of unemployment throughout the labor force can change the meaning and significance of the aggregate data. For example, a minority of people may account for the bulk of the total weeks of unemployment within any given period. The same unemployment statistic, however, could indicate a situation in which most people experience a short bout of unemployment at some time, but each only loses a small proportion of his or her potential work time. Not much information is available on this issue primarily because of the difficulties in obtaining unemployment spell histories. Nevertheless, data from the "Work Experience" supplement of the CPS can provide some aggregate information on the distribution of weeks of unemployment. These data will be supplemented by recent information from the Panel Studies on Income Dynamics Survey conducted by the University of Michigan.

Table 6. The distribution of weeks of unemployment, 1969, 1975, and 1978

Duration measure	1969	1975	1978
Percent of labor force unemployed by duration:			
Year-round workers[1]	1.5	0.8	0.6
Other workers[2]			
1 to 4 weeks	4.5	4.5	4.2
5 to 14 weeks	3.8	6.1	5.5
15 to 26 weeks	1.7	4.4	3.2
More than 26 weeks	1.0	4.4	2.3
Weeks unemployment by duration as a percent of total weeks unemployed:			
Year-round workers[1]	1.8	.4	.4
Other workers[2]			
1 to 4 weeks[3]	9.0	3.4	4.8
5 to 14 weeks	28.5	17.3	23.4
15 to 26 weeks	28.3	27.2	29.4
More than 26 weeks	32.5	51.7	42.2

[1] Year-round workers experienced 1 to 2 weeks of unemployment.

[2] Other workers includes those who looked for work but did not work during the year.

[3] Calculations are based on the mid-range of the unemployment duration categories.

Table 6 contains the CPS "work experience" information. It is critical to understand the limitations of the data. From table 2, it was noted that, in the aggregate, the probability of escaping unemployment declined significantly with time unemployed. This will naturally tend to show up as a concentration of unemployment in longer spells simply because the longer a spell has lasted, the lower the probability of escape. Even if the probability of escape for each individual is constant, a large share of unemployment would be the result of the individuals who have lower escape probabilities. To get the "true" picture one must be able to test for heterogeneity between individuals—sorting—or duration dependence—as unemployment lengthens, the escape rate for individuals declines.[32]

Given these caveats, table 6 contains some interesting information. The concentration of unemployment is stark. In 1969, the 1 percent of the labor force unemployed more than 27 weeks accounted for 32 percent of total weeks unemployed. There is also a pronounced cyclical pattern to the distribution. In 1975, the proportion of the labor force unemployed at least 27 weeks jumped fourfold from 1969 and accounted for 52 percent of total unemployment. The distribution in 1978 lies between 1969 and 1975.

Because table 6 provides only annual data and contains no information on spells of unemployment, it is not possible to determine whether the same group of people become unemployed over and over again. Perhaps the most important information is the cyclical pattern; it is exactly what one would predict from an examination of escape probabilities. If nothing else, it is clear that a key to understanding unemployment duration involves explaining its behavior over the course of a business cycle.

A last bit of information on the concentration of unemployment is from a study on the 10-year (1968–77) work history of married adult males.[33] Although the data suffer many of the defects of table 6 (multiple spells in a year are not measured) it does follow the same individuals over a long period of time. The results are fairly consistent with the CPS "work experience" data. A large number of people experienced some unemployment over the 10-year period, but just 5 percent accounted for about half (46.6 percent) of the total time unemployed among the entire sample. The poor, blue-collar workers, and construction workers were disproportionately concentrated in this small group.

Some analysts have claimed such data challenge most theories of the labor market (for example, on search and turnover, dual labor markets, and others) because these theories focus on the relative brevity of completed spells of unemployment and are based on the notion that, except in recessions, jobs are readily available. Yet, the data are neither capable of evaluating the efficacy of various theories nor, more importantly, are they inconsistent with different versions of each theory. The data show only that some people are unemployed a lot; they do not show that jobs are never held between periods of joblessness. Data encompassing unemployment and employment spell histories would be necessary to determine the existence of a group of workers who are more or less permanently unemployed.

THIS ARTICLE has presented one method to estimate the expected duration of a completed spell of unemployment and the number of spells of unemployment. Data and measurement problems associated with unemployment were also discussed. From this review, it is clear that five issues are most important in analyzing unemployment patterns. First, a sharp conceptual distinction exists when measuring the duration of completed spells of unemployment and in-progress spells. In general, the estimates of the average length of a completed spell were about 75 percent of the average of an in-progress spell. Second, duration statistics may be a very unreliable guide on the relative ease of finding work; one necessary complement to the data is analysis of the causes of labor force withdrawal. Third, it is important to gauge the importance of multiple spells of unemployment to adequately interpret duration data. Fourth, information on the concentration of unemployment is important. For example, while most spells of unemployment may be relatively short, most unemployment may be accounted for by those with many spells or with long periods of joblessness. Last, and very important, an understanding of the business cycle and its impact on the labor market is essential to any analysis of unemployment duration. □

FOOTNOTES

[1] See Hyman Kaitz, "Analyzing the length of spells of unemployment," *Monthly Labor Review*, November 1970, pp. 11–20. Kaitz's path-breaking work was the first to estimate the duration of completed spells of unemployment in the United States. For an early application to data from England, see R.F. Fowler, "Duration of Unemployment on the Register of the Wholly Unemployed," Studies in Official Statistics, Research Series 1, London, Her Majesty's Stationary Office, 1968.

[2] Stephen W. Salant, "Search Theory and Duration Data: A Theory of Sorts," *Quarterly Journal of Economics*, February 1977, pp. 39–57 George Akerlof and Brian Main, "Unemployment Spells and Unemployment Experience," Special Studies Paper, Federal Reserve Board, Number 123, Oct. 23, 1978; and Robert Frank, "How Long is a Spell of Unemployment," *Econometrica*, March 1978, pp. 285–301.

[3] Salant, "Search Theory . . . ," has shown that three propositions concerning the measure of interrupted and completed spells of unemployment follow from a knowledge of escape rates: (1) If the probability of escape increases the longer one is unemployed, the expected length of a completed spell, E(C), is greater than the expected length of an interrupted spell, E(T). This results from the fact that interruption bias predominates; (2) If the probability of escape is constant, the two measures, E(C) and E(T), are the same. In this case, the effects of interruption bias and length bias exactly offset each other; and (3) if the probability of escape declines, E(T) is greater than E(C), and the effect of length bias predominates.

[4] See Kaitz, "Analyzing . . . ," for one example of this.

[20] Both George Perry, "Unemployment Flows . . . ," and Stephen Marston, "Employment Instability . . . ," have emphasized the problems with interpreting duration data because of the possibility of exiting from the labor force. Also see Stuart Garfinkel, "The outcome of a spell of unemployment," *Monthly Labor Review,* January 1977, pp. 54–57; and T. Aldrich Finegan, " The Measurement, Behavior, and Classification of Discouraged Workers," National Commission on Employment and Unemployment Statistics, Background Paper No. 12, June 1978.

[21] Clark and Summers, "Labor Market . . . ," p. 19. Exit from the labor force varies widely among different demographic groups and there may be different explanations for each. Thus, some caution is required in interpretating the aggregate statistics. Furthermore, unless otherwise noted, we have assumed that the labor force movements are real and not the result of misclassification or other errors. Lastly, none of our data are appropriate for explaining unemployment differentials among social groups, for example, teenagers and adults.

[22] Perry, "Unemployment Flows . . . ," pp. 270–75.

[23] See Ralph Smith, "A Simulation Model of the Demographic Composition of Employment, Unemployment and Labor Force Participation," in Ronald Ehrenberg, ed., *Research in Labor Economics,* Volume 1 (Greenwich, Conn., JAI Press, 1977) pp. 259–304; and Ralph Smith and Charles Holt, "Recession and the Employment of Demographic Groups," *Brookings Papers on Economic Activity,* No. 3, 1974, pp. 737–60.

[24] Clark and Summers, "Labor Market . . . ," p. 26. To be classified as discouraged a person must *only* cite reasons of discouragement. If the respondent cites other reasons, such as home responsibilities, even if along with reasons of discouragement, the person is not counted as discouraged. For a more in-depth analysis of discouraged workers, see Finegan, "The Measurement . . . ," pp. 3–11.

[25] Another hypothesis is that the unemployed remain in the labor force in order to collect unemployment compensation. When the benefits are exhausted they withdraw from the labor force. It is doubtful that this is very important in explaining labor force exits overall because the probability of withdrawal is greatest among those groups less likely to be eligible for benefits. In addition, over time, there seems to be no trend in the proportion of unemployment spells that ended in withdrawal, yet there have been important modifications in unemployment compensation, for example, extensions in the benefit period. There is some (tentative) evidence that the unemployment insurance system may induce some labor force participation among those eligible to receive benefits who otherwise might have stopped looking for work. See Gary Solon, "Labor Supply Effects of Extended Unemployment Benefits," *Journal of Human Resources,* Spring 1979, pp. 247–55.

[26] Clark and Summers, "Labor Market . . . , pp. 28–31.

[27] Clark and Summers, "Labor Market . . . ," p. 31.

[28] See Perry, "Unemployment . . . ," pp. 248–78; Marston, "Employment Instability . . . ," pp. 169–210; Richard Disney, "Recurrent Spells and the Concentration of Unemployment in Great Britain," *Economic Journal,* March 1979, pp. 109–19; Richard Freeman and Robert Frank, "The Distribution of the Unemployment Burden," *Review of Economics and Statistics,* August 1978, pp. 380–91; Robert Hall, "Turnover in the Labor Force," *Brookings Paper on Economic Activity,* No. 3, 1972, pp. 709–56; and David Stevens and McNeil Gima, "The 'Incidence' Theory of Black-White Unemployment Differentials Revisited," Unpublished paper, University of Missouri, 1975, pp. 1–16.

[29] See Dale Morgenstern and Nancy Barrett, "The Retrospective Bias in Unemployment Reporting by Sex, Race, and Age," *Journal of the American Statistical Association,* June 1974, p. 356. Clark and Summers, "Labor Market . . . ," argue that a benefit of the work experience data is that its retrospective nature reduces problems associated with "spurious" movements into and out of the labor force.

[30] Stevens and Gima, "The 'Incidence' Theory . . . ," pp. 5–7.

[31] Similar results have been obtained using data from the National Longitudinal Survey. See Akerloff and Main, "Unemployment Experience . . . , " pp. 14–18.

[32] One attempt to test this using data from England is contained in A. McGregor, "Unemployment Duration . . . ," pp. 693–706. The results, though not flawless, suggest that individual escape rates do decline with time unemployed even after controlling for other characteristics.

[33] Martha Hill and Mary Corcoran, "Unemployment among family men: A 10-year longitudinal study," *Monthly Labor Review,* November 1979, pp. 19–23. Disney, "Recurrent Spells . . . ," presents estimates of the concentration of unemployment among three cohorts of males in England. The results are similar to those of Hill and Corcoran.

Construction machinery industry posts slow rise in productivity

Growth was slower than manufacturing average in 1958–78, with 4 years recording declines, despite considerable capital expenditure and new technology; 1977–78, however, showed strong productivity advances

JOHN DUKE

Output per employee-hour in the construction machinery industry rose at an average annual rate of 2.0 percent between 1958 and 1978,[1] compared with a 2.6-percent rate for the entire manufacturing sector. This was the result of an average annual increase of 4.5 percent in output, and 2.5 percent in employee-hours. (See table 1.) The long-term trend was marked by cyclical swings. In 1977 and 1978, there were strong gains.

Productivity declines occurred in 4 of the 21 years between 1958 and 1978. In two of them, 1959 and 1968, increases in employee-hours exceeded output gains. In the other two years of decline, 1960 and 1975, productivity fell because sharp drops in output exceeded reductions in employee-hours.

The long-term gain in productivity resulted mainly from innovations in the machining and welding operations at the industry's plants, and from improvements in handling and storing materials. Computerization of accounting functions also helped to increase productivity.

Following 2 years of decline in 1959 and 1960, productivity increased at an average annual rate of 4.8 percent per year during 1960–65, induced largely by a strong rise in output, averaging 9.1 percent per year. Between 1965 and 1970, productivity slowed to an average rate of only 0.8 percent per year, as output gains slackened to an average annual rate of 2.4 percent. Productivity rebounded once again in the early 1970's, increasing at an average annual rate of 4.4 percent between 1970 and 1974, with output increasing 11.8 percent. Output per employee-hour declined 6.9 percent in 1975, as output fell 12.8 percent, but rose again in 1976, by 1.6 percent, when a 4.7-percent drop in output was exceeded by a decrease in employee-hours. Productivity rose by 5.0 percent in 1977 and 2.8 percent in 1978 as output recorded strong gains.

The construction equipment industry produces a variety of machines for earthmoving, hauling, lifting, grading, and paving. The machines are used not only in the construction industry, but also in mining, logging, railroad track maintenance, agriculture, and military operations.

Most construction equipment has not undergone major change over the past 20 years, but there has been a steady increase in the size, power, and flexibility of the machinery produced. For example, in 1958 only about 15 percent of new crawler tractors had greater than 160 horsepower. By 1977, nearly 40 percent were that powerful.[2] Demand for more powerful machines has come from construction contractors seeking to boost the efficiency of their operations.

Table 1. Productivity and related indexes for the construction machinery industry

Year	Output per employee-hour			Output	Employee-hours		
	All employees	Production workers	Nonproduction workers		All employees	Production workers	Nonproduction workers
1958	90.1	97.4	73.0	62.6	69.5	64.3	85.8
1959	84.4	86.3	78.9	74.0	87.7	85.7	93.8
1960	75.5	80.4	63.7	63.2	83.7	78.6	99.2
1961	82.7	86.8	72.6	59.0	71.3	68.0	81.3
1962	89.8	92.0	83.6	67.5	75.2	73.4	80.7
1963	90.9	91.3	89.7	73.1	80.4	80.1	81.5
1964	94.4	93.2	98.3	85.4	90.5	91.6	86.9
1965	96.9	95.3	102.2	91.4	94.3	95.9	89.4
1966	98.5	94.9	111.9	94.3	95.7	99.4	84.3

John Duke is an economist in the Division of Industry Productivity Studies, Bureau of Labor Statistics.

Output doubles

Output of construction machinery more than doubled over the 1958–78 period. The increase was generated by expanding overall construction activity and strong export demand. The value of total new construction (in constant dollars) rose 60 percent during 1958–72, before turning flat in 1973, and dropping sharply in 1974 and 1975. Since 1975, new construction has risen nearly 20 percent.[3] Exports of construction machinery, which currently account for nearly one-third of U.S. production, almost quadrupled between 1960 and the mid-1970's. Construction and related activities in foreign countries during this period rose considerably faster than did U.S. construction, providing a strong impetus to U.S. exports.[4]

Although overall construction activity remains the most important determinant of construction equipment output, the cyclical and year-to-year variations in construction equipment output during 1958–78 did not always closely follow changes in construction activity. One reason is that the use of construction equipment varies greatly, depending upon the type of construction. The different types have widely varying ratios of cost between construction equipment and total contract.[5] For example, in the construction of single family housing, machinery is a relatively minor factor, while for projects such as sewer lines and highways, large amounts of construction equipment are employed. Some types of construction machinery, such as crawler tractors and tractor shovel loaders, are used to prepare many kinds of construction sites, making it difficult to associate changes in production of these units with those in specific construction markets.

Changes in output in the industry were large over the period. In only 5 years were year-to-year output changes less than 6 percent. After an 18-percent increase in 1959, when nearly all segments of construction activity showed strong gains, output fell by 15 percent in 1960. This decline resulted from a downturn in many construction markets, and from the existence of a large inventory of machines in operation. The downturn continued with a 7-percent drop in 1961. Sustained high levels of construction and an expansion in exports during 1962–65 led to strong increases in construction machinery output, particularly in 1962 and 1964, 14 percent and 17 percent, respectively.

After 1965, output gains narrowed, as activity in many construction markets dropped from the high levels of the early 1960's. An acceleration in exports during this period helped maintain continued increases in output. Declines in construction activity during 1969–70 led to an output drop of 7 percent in 1970 and 5 percent in 1971. But output rebounded during 1972–74, posting consecutive gains of 21 percent, 16 percent, and 10 percent for the 3-year period. Expanding construction activity boosted demand for construction equipment in the United States; foreign demand for U.S.-built machinery soared during 1973–74, aided by changes in the relative values of national currencies. The severe drop in construction activity during 1974–75 caused machinery output to fall sharply, 13 percent in 1975, despite continued strength in foreign demand. The decline continued into 1976, with a 5-percent decrease. Output rebounded in 1977 and 1978, rising 11 and 12 percent, in response to the upturn in construction.

Employment and investment

The construction machinery industry is characterized by large scale production. In 1977, the average plant employed 169 persons, more than triple the average of 53 employees for the entire manufacturing sector. Establishments with 500 or more employees account for more than two-thirds of industry's value of shipments. Industry operations are concentrated in the North Central region of the United States, with more than three-fourths of employment located in those States.

Between 1958 and 1977, the number of establishments rose 57 percent to 910. The increase was somewhat less than the gain in employment, resulting in a slight rise in the average number of employees per plant. The increase in establishments was associated with a slight shift in industry operations to the Southern region. The number of establishments in the South doubled during 1958–72 to 162, raising the South's regional share of employment in the industry from 5 to 11 percent.

Currently at 165,000 persons, employment in the construction machinery industry rose 74 percent during 1958–78. However, the upward trend was not steady; employee-hours fluctuated considerably over the period, because of large swings in output. For example, output rose 18.2 percent in 1959, with a 26.2-percent gain in employee-hours. In 1961, employee-hours dropped 14.8 percent, following 2 consecutive years of declines in output. Sharp output increases in 1964, 1972, and 1973 accompanied large increases in employee-hours in those years.

Production workers accounted for 72 percent of total employment in the industry during 1978, virtually unchanged from the 1958 proportion, and about the same as the manufacturing average. Women accounted for only 8 percent of total employment, compared with 30 percent for manufacturing as a whole. Hourly earnings averaged $8.01 in the industry, about 30 percent above the manufacturing average. Regional and skill factors as well as the high degree of unionization account for the higher wage levels.[6] The North Central region, where construction machinery manufacturing operations are concentrated, had earnings about 10 percent above the average for all manufacturing, according to 1972 Census data. Skill levels in the industry are also above the average for manufacturing in general. Professional, technical, and kindred workers accounted for 11.8 percent of construction machinery employees, while total manufacturing had 10.2 percent of its employees in such positions. Crafts and kindred workers represented 21.4 percent of workers in the industry, while manufacturing in general had 19.7 percent of its employees in these positions. Although the proportion of operatives (less-skilled employees) was only slightly lower (39.4 percent) for this industry than for the manufacturing average (42.2 percent), almost half of these employees in construction machinery were semiskilled metalworkers, whose earnings exceed that of most other groups of operatives.

Labor turnover in the industry has been well below that for all manufacturing during 1958–78. For example, in the average month of the study, quits per 100 employees were 1.0 for construction machinery and 1.9 for all manufacturing. New hires and layoffs per month averaged 1.7 and 1.0 percent, respectively, for this industry, compared with 2.8 and 1.6 for all manufacturing.[7] The comparatively low rates of turnover reflect the above-average skill levels and high degree of unionization in the industry. Firms are more reluctant to lay off skilled employees during downturns, because of the cost of training new employees when production again increases. Also, unionized workers resign less frequently.[8]

Capital expenditures per employee averaged $3,212 in 1977, considerably above the $2,587 average for all of manufacturing. However, above-average capital expenditures did not occur in the industry until the mid-1970's. Industry expenditures per employee in 1958 were below that of all manufacturing but rose faster during the study period, 10 percent per year on average, compared with 8 percent. Total assets per employee per establishment were $21,879 in 1976, below the $22,326 all-manufacturing average, but they had risen slightly faster than average since the early 1960's. Nearly half of the capital expenditures for equipment during the mid-1960's went for machine tools.[9] Although no precise data are available on the proportion of machine tools that are numerically controlled, industry sources indicate that the use of these tools increased significantly during the late 1960's and the 1970's.

Technological gains

The basic processes in the production of construction machinery, parts machining, heat treating, welding and fabrication, and assembly, did not change significantly during 1958–78. However, there were productivity gains from gradual technological improvements in them. Capital investment in improved machine tools with increased horsepower, and faster operating speeds, have increased productivity in the machining processes. Numerical control has speeded up the machining of parts. This involves the automatic setting of machining angles, speeds, and feeds by electronic control units. Tools such as gear cutting and grinding machines have been used for many years, but the operator had to manually place the material into position, set the speeds for the feeding and machining of the material, and monitor the machining process. Numerical control is considerably faster and allows one operator to monitor several machines.[10] Since the mid-1970's, the industry has been investing in manufacturing systems, comprised of groups of machine tools linked by material handling equipment, which greatly reduce machine set-up and component handling time.[11]

The heat treating process has been largely unaffected by technological changes in the industry. Machined parts are fed into a furnace, heated, and then quenched in oil or water. This process strengthens the parts and relieves stress, for greater durability. Feeding parts through the furnace automatically has been introduced, but the process has remained mostly a manual operation.

There have been significant labor-saving innovations in welding operations in construction machinery manufacturing plants during 1958–78. In earlier years, the most prevalent welding techniques produced "slag," a film of debris that had to be cleaned from the weld surface. In the early 1960's, improved welding techniques were introduced which produced very little slag. Their rapid diffusion greatly reduced the labor time in cleaning welded parts. Also, the new welding process is quicker; the welding electrode is continuously fed to the welding surface. Under the old process, individual "sticks" of electrode material were used and replaced manually.

Other improvements include the introduction, in some plants, of conveyor systems to transfer parts between stations. These systems, which have been replacing hand carts, reduce bottlenecks in the production flow. The introduction of computers has saved labor in purchasing and accounting functions, and has helped maintain better inventory control.[12]

Future developments

Although the pace of construction activity is difficult to predict, some factors that will probably affect construction machinery demand in the near future are evident. The interstate highway system, which helped boost purchases of construction equipment in the late 1950's and 1960's, is more than 90 percent complete, and real expenditures for construction of new highways and streets have trended downward since 1970. In addition, export demand for construction equipment, which had risen rapidly in the early and mid-1970's, may stabilize. Foreign manufacturers are becoming increasingly competitive in the construction machinery market, and U.S. subsidiaries abroad are also increasing their market share. These factors portend a slackening in the years ahead in the booming export market for U.S.-built construction equipment. However, offsetting these factors will be increased demand from specific domestic markets. Sewer and water projects are expected to increase significantly, due to pollution control mandates. Also, mining, particularly strip-mining of coal, should show a strong rise in the near future, increasing the demand for large excavating and earthmoving machines. Overall, construction equipment output is expected to grow about 3 percent per year over the next 5 years, significantly below the long-term rate.[13]

The slackening in demand anticipated for the next few years will tend to retard productivity improvement. However, the quickening pace of adoption of technological innovations should offset this to some extent. Investment in numerically controlled machine tools is expected to increase, with emphasis on more flexible machines that can perform a number of different functions. Many machines in the industry have limited capabilities, and the set up and material handling time inherent in them have proven to be bottlenecks in the production flow. The low volume of production for individual types of construction equipment, combined with the specialized nature of most conventional machine tools, has limited the diffusion of numerical control. In recent years, however, advanced manufacturing systems have been developed which greatly facilitate smooth production flow and which are efficient for the low-to-medium volume in the industry. Capital expenditures increased greatly during the mid-1970's and there is evidence that a significant amount is being invested in these advanced systems.[14] The industry's substantial investment in this equipment should cause productivity gains to accelerate. □

FOOTNOTES

[1] The construction machinery industry is composed of establishments primarily engaged in producing heavy machinery and equipment used by the construction industries; it produces items such as bulldozers, concrete mixers, cranes, pavers, and power shovels. It is designated as industry number 3531 in the *1972 Standard Industrial Classification Manual* of the Office of Management and Budget. Data for this productivity measure first became available in 1958. All average annual rates of change are based on the linear least squares trend of the logarithms of the index numbers. A technical note describing the methods used in the construction of the indexes is available upon request.

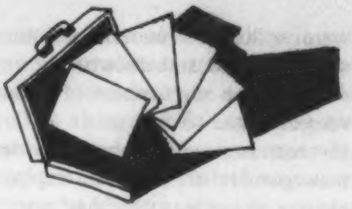
APPENDIX: Measurement techniques and limitations

The productivity indexes in this study measure the change over time in industry output per unit of labor input. They do not measure the specific contribution of labor, but reflect the influence of many factors such as technology, capital investment, and managerial skills, as well as skill and effort of the work force.

The output index for this industry is based upon value of shipments data, published by the Bureau of the Census. Detailed data from the Census of Manufactures for 1958, 1963, 1967, and 1972 were used to derive benchmark indexes, to which the annual indexes for intervening years, based on the Annual Survey of Manufactures, were adjusted. The value of shipments of the various product classes were adjusted for price changes by appropriate Producer Price Indexes to derive constant dollar output measures. These, in turn, were combined with employee-hour weights to derive the overall output measure. Employment and employee-hour indexes were derived from Census and Bureau of Labor Statistics data. Employees and employee-hours are considered homogeneous and additive, and thus do not reflect changes in the qualitative aspects of labor such as skill and experience of persons constituting the aggregate.

Conference Papers



Although the phrase "quality of worklife" has been part of the industrial relations vocabulary for more than a decade, the concept has not yet found wide acceptance. Some practitioners view it with enthusiasm, others with cynicism. Among the former are Stephen H. Fuller, a vice president of the General Motors Corp., Irving Bluestone, who recently retired as a vice president of the United Auto Workers, and Barry A. Macy, director of the Texas Center for Productivity and Quality of Work Life. Fuller and Macy spoke at last December's annual meeting of the Industrial Relations Research Association in Atlanta, Ga., Bluestone at a December conference on "Critical Economic and Work Force Issues Facing Western Nations," sponsored by the Work in America Institute and the International Institute of Labor Studies in Washington, D.C.

How quality-of-worklife projects work for General Motors

STEPHEN H. FULLER

Quality of worklife is not a happiness program, although happy employees may certainly be a byproduct. It is not a personnel department program, although quality of worklife has important implications for personnel management. It is not a sublte employee incentive program, although employees motivated to achieving the goals of the organization certainly ought to be one of the outcomes. And, it is not another productivity program, although better productivity is certainly one of the important results.

Quality of worklife *is* all of these things and more:

- A continuing process, not something that can be turned on today and turned off tomorrow.
- Using all resources, especially human resources, better today than yesterday . . . and even better tomorrow.
- Developing among all members of an organization an awareness and understanding of the concerns and needs of others, and a willingness to be more responsive to those concerns and needs.
- Improving the way things get done to assure the long-term effectiveness and success of organizations.

General Motors is making a concerted effort to improve the quality of worklife for its employees. Projects are underway in most North American operations and in many overseas operations as well. The approach was not developed overnight. It evolved from a philosophy of management, shaped by events and experiences occurring over a considerable period of time.

A key component of our quality-of-worklife process is union participation. Quality of worklife became a joint effort of General Motors and the United Auto Workers in 1973, when a National Committee to Improve the Quality of Work Life was established. Representing the UAW on the committee are two officials of the international union. The corporation is represented by two personnel officers. The committee meets periodically to discuss activities underway in the corporation. One of its chief functions is to educate executives of the union and the corporation in order to encourage cooperative quality-of-worklife ventures at the local level.

The committee adopted minimum standards to assure that every GM plant has the basics of a quality-of-worklife effort. Each operation is expected to have:

- A group to oversee the quality of worklife process.
- A statement of long-term objectives incorporating quality of worklife along with other desirable business targets.
- Regular measurement of quality of worklife.
- Seminars and other activities to make the organization more knowledgeable about quality-of-worklife concepts and techniques.
- Adequate internal resources and skills to assure the developmental process is moving ahead and accomplishing its objectives.

Approaches vary

A quality-of-worklife improvement program is mandatory at GM, however, specific approaches are optional. Following are some examples of approaches being applied at existing and new plants.

A decade ago, one of our assembly plants could have been characterized as a problem plant. There was an air of hostility between management and the union. Costs were high. Performance was poor. Something had to be done. Fortunately, the local management and union

---

Stephen H. Fuller is a vice president of General Motors Corp.

were willing to undertake some initiatives. As both sides explored and discussed their mutual problems and concerns, an atmosphere of understanding and mutual respect began to emerge. In 1972, the plant faced a major rearrangement which provided an opportunity for management to involve employees in planning the change, something that had not been done before. The rearrangement went well, due, in part, to the employees' suggestions.

Then, following the lead set by the GM-UAW National Quality of Work Life Committee, plant management and the union established their own committee. In 1977, management and the union initiated a 3-day training program providing employees at the plant training in team problem-solving. Although the program was voluntary, nearly all of the 3,600 employees participated. Today, employee morale at that plant is high, grievances are only a fraction of what they were a decade ago, and the plant has become one of the best-performing assembly plants at General Motors.

Another GM plant abandoned the traditional organizational structure a few years ago. Today, the plant is organized into six business teams, each consisting of the necessary production activities and support elements: engineering, scheduling, material handling, quality control, maintenance, and accounting. The system has made support employees an integral part of the plant's business operations. The quality-control circle concept, which has flourished in Japan and is being introduced by a growing number of firms in this country, has been incorporated into the business-team structure. The circle concept gives employees the opportunity to meet regularly to discuss problems affecting their work environment and the plant's performance.

These are only two of many approaches underway in established GM plants. New plants provide a unique opportunity to design an organization from a blank sheet of paper. Free from the constraints of past practice and stereotyped roles, each plant is an opportunity to introduce new approaches.

There are three important considerations underlying quality-of-worklife initiatives in new plants: (1) there is no best system or organizational design, (2) there is an ongoing interaction among the parts of the system—a change in one part of the system can have a significant impact on the entire system, and (3) each part of the system must reinforce consistency of operations and facilitate employee involvement.

To achieve an organizational system in which each part is congruent with the rest, careful consideration is given to the basic values, principles, and objectives held by local management. The development of a philosophy and goals is viewed as a necessary first step in the planning process. (The philosophy and goals are statements reflecting the local management's beliefs about people and work and the relationship between those beliefs and the plant's objectives.)

A team concept is a major feature of many new GM plants. Job rotation within the team is encouraged. Employees thus acquire broader skills which, in turn, allows for greater flexibility in performing all of the tasks within the team. This concept tends to promote employee involvement and satisfaction, and to minimize the disruptive effects of occasional absenteeism and turnover. Employees are encouraged to move from one team to another once they have learned all of the jobs in the team. This further adds to the fulfillment of employee interests and to the expansion of experiences and achievements.

The team concept encourages employee responsibility and involvement. For example, employees may have responsibility for training team members; assessing individual team members' progress in satisfactorily performing job assignments; forecasting efficiency, scrap, and manpower requirements in their operating areas; recommending corrective action for improper conduct of team members; contributing to the selection of new employees; selecting team leaders; and maintaining operation of tools and equipment within process standards.

Employee-management communications essential. In our plants, emphasis is placed on effective communication, particularly face-to-face communication. It begins with the orientation, which includes, in addition to traditional topics, a thorough review of the plant's philosophy and goals. Periodic plant meetings and team meetings are used to discuss aspects of the business—for example, quality, schedules, scrap and rework, housekeeping, safety, employee facilities, production facilities, and customer orders. There also is ample opportunity for employees to discuss their concerns with management.

The role of the personnel department at General Motors is to facilitate the development of the quality-of-worklife process by consulting with management, with employees, and with their elected representatives. Well-conceived and effectively administered personnel programs are absolutely essential for a strong quality-of-worklife effort.

One such program is a system of redress for those employees not represented by a union. A formal "open door policy" is one approach, but it must have the support of all levels of management. An effective appraisal system for all employees, including managers and executives, also is essential. The appraisal also should evaluate managers' support and implementation of quality-of-worklife principles.

Training for all employees is an absolute necessity. If employees are to be involved in the decisionmaking process, if they are to grow and develop, they must have the opportunity to acquire the necessary knowledge and skills.

Finally, it is necessary to have a statement of philosophy that spells out the general role workers have in the organization and how they are to be treated. A statement of philosophy that represents the consensus of senior management provides a basis for encouraging managerial behavior consistent across plants and functions. The philosophy also lets employees know how they can expect to be treated.

All efforts at General Motors require a firm commitment at the top levels of the corporation. Such support, combined with a variety of successful projects has led to the creation of a quality-of-worklife program in nearly all plants. This does not mean that GM has all the answers or that quality of worklife is fully developed in General Motors. There is much to be done, but the corporation is on the right track and making progress.

Future of the projects

An important shift in union-management relations began in the decade of the 1970's. Unions and management showed a willingness to explore new alternatives and, in some instances, levels of cooperation once thought impossible produced dramatic results. What about the decade of the 1980's? What is the future of quality of worklife in America?

Two critical forces will have a significant impact on the future of quality-of-worklife projects. One is the changing values of workers. Increased sense of entitlement, disregard for authority, and a general low esteem of our institutions have been major factors in the developmental years of quality of worklife. Today's workers place less emphasis on material achievement and more on personal fulfillment. The value shift of Americans will significantly impact the future of quality of worklife.

The second force is economic. While business is being challenged to respond to dramatically changing values, our country is facing economic problems. The fact is, the United States is locked in a fiercely competitive economic struggle which could have either a positive or negative impact on quality of worklife—positive if it leads to innovative solutions and negative if it results in simply greater emphasis on traditional approaches.

Our Nation's poor productivity improvement rate is a major factor contributing to our economic ills. The problem has not come about overnight. Between 1947 and 1967, output per hour of work in the United States nearly doubled. Since 1967, output per hour worked has risen only about one-fifth. And in 1978, the U.S. productivity growth rate was an alarming one-half of 1 percent, a dismal performance compared to the rate of growth of other major industrial nations, particularly Japan.

In the past, America has been able to compete with cheap overseas labor because of our capital investment. In 1978, however, capital investment per worker in this country amounted to less than $3,700, compared with nearly $5,000 per Japanese worker. There are many factors in addition to capital investment which contribute to Japan's envious productivity growth rate. Among them are government policies and programs that actively support economic expansion, technological innovation, harmonious union-management relations, and a totally dedicated work force. Group goals are far more important than individual successes in the Japanese structure.

I do not think we can ignore the traits present in the Japanese system. In this country, we have been overly loyal to organizational tradition. But, today, we cannot afford not to take new risks. The joint efforts of business, government, and labor are essential if we are to respond to the needs of a changing workforce and resolve our economic problems.

Stumbling blocks. As we push forward the frontiers of quality of worklife there are some formidable obstacles to overcome. One is the issue of control. Should control be viewed as external to the individual, as provided for through a supervisor and shop rules? Or should it lie within the individual's self-regulating ability and value system and based upon mutual influence and interest that leads to "win-win" rather than "win-lose" relationships? Moving from external to self-regulating sources of control would seem to be consistent with the quality-of-worklife viewpoint. How much training and how much information is management willing to provide if employees are to be self-regulating? Many organizations in the past have been cautious about sharing information, particularly financial information, for fear employees will use this knowledge to make "unfair" claims on the enterprise. □

How quality-of-worklife projects work for the United Auto Workers

IRVING BLUESTONE

In 1973, in bargaining with General Motors Corp. for a new national agreement, the United Auto Workers (UAW) proposed the establishment of a National Joint Committee to Improve the Quality of Worklife. The parties agreed to a document which set forth their gen-

---

Irving Bluestone recently retired as a vice president of the United Auto Workers and director of the union's General Motors department.

eral understanding on the subject and pledged to urge their respective local managements and local unions to cooperate "in (quality-of-worklife) experiments and projects."

How, where, and when to go about the task were left open for the parties to consider. Over time, certain generalized concepts have become accepted. However, the approach varies in each situation because the program is not imposed from the top down, but must be cooperatively and voluntarily developed and implemented from the bottom up—at the local union-management level.

Today, there are approximately 50 quality-of-worklife programs in UAW-GM bargaining units. Most are still in the early stages—an indication that such programs are not "instant utopias" but rather follow a slow, cautious, deliberate pace.

How did the UAW and GM go about setting up a quality-of-worklife program? What were the "nuts and bolts" steps taken and how were they implemented? While no two projects are identical, the following describes in concrete terms what happened.

The fact that the National Joint Committee to Improve the Quality of Worklife exists and urges the local parties to consider undertaking a project supplies the initiative to create interest in the subject. A local management may contact the local union shop committee (or vice versa) suggesting the local parties discuss the possibility of initiating a quality-of-worklife project. The local union as a rule will contact the international union and ask for a thorough explanation of the concept, how it works, what it entails, and its advantages and disadvantages.

An international union representative will meet with the local union official and describe in detail the meaning and purpose of the concept and what has been done elsewhere and why. The representative will set forth certain guiding principles which are usually agreed upon as a basis for proceeding:

- There must be no increase in production standards as a result of the quality-of-worklife program—an assurance against speed-up. (Naturally, increased production due to technological change is another matter.)
- There must be no loss of jobs as a result of the program—an assurance of job security. (Obviously, layoffs due to business cycles are another matter.)
- The provisions of the national agreement and of the local agreements and practices remain inviolable.
- The program will be voluntary. No worker will be compelled to participate.
- The union representatives will be involved in all aspects of the program—sharing with management equally in the development and implementation of the program.
- Either party may cancel the program at any time—an assurance against either being tied to a project in which it has lost faith.

The local, after full discussion, will decide whether to proceed. It is advised to "go slow," to experiment with a pilot project at first and approach the program on a "cut and try" basis. The local understands that normal collective bargaining continues, that a quality-of-worklife program will not solve all the plant problems.

In the UAW-GM approach, no separate quality-of-worklife committee is formed. The local union shop committee—the elected representatives of the workers for purposes of handling grievances and bargaining—is the union counterpart in the program. This avoids any conflict in determining which subjects fall within the purview of adversarial collective bargaining and which are subject to the cooperative effort of quality of worklife.

A quality-of-worklife program cannot succeed unless the local parties develop a collective bargaining climate of mutual respect, a climate in which solving problems supersedes beating the other party down. Therefore, the first phase, before the parties can move significantly toward worker participation programs, entails fostering a mutually respectful relationship as the groundwork for a program which will involve the workers directly.

This is no overnight task. It may take months of getting together and talking things through. Essentially the problem is attitudinal, and breaking down distrust and cynicism on both sides is a slow but extremely rewarding process.

Once phase one is well underway, the road is paved for the local parties to embark on pilot projects in which workers on a volunteer basis become involved in problem solving and participate in making decisions regarding the workplace which, heretofore, have been denied them. By now, the parties have learned to work together more cooperatively. Without pervasive rancor and suspicion beclouding their efforts, they can join mutually in analyzing the problems which trouble the workers and create the opportunity for workers to help resolve them.

The overriding consideration is that all decisions are by mutual desire and consent at the local level. Neither the corporation nor the international union instructs the local parties; each is merely a catalyst (to advise and consult) when called upon.

There is ample evidence that the introduction of a quality-of-worklife program has a salubrious effect upon the adversarial collective bargaining system. For example, simultaneously with national negotiations between the UAW and GM, the local parties negotiate on local issues, including seniority, transfer, shift preference, equalization of overtime agreements, and other proposals to improve working conditions and health and safety, grievances, and other issues. Of the first 90 local settlements in 1979, all of which were accomplished without a strike threat, 44 were engaged in some stage of a quality-of-worklife program. Considering there are about 50 programs at GM, this represents a noteworthy achievement.

Studies at locations where a quality-of-worklife program has existed long enough to be meaningful indicate a more constructive collective bargaining relationship; a more satisfied workforce; improved product quality; a reduction in grievance handling, absenteeism, labor turnover, and disciplinary layoffs and discharges.

These are all mutually desirable objectives; they represent benefits for the workers and advantages for both the union and the management. But above all, from the workers' point of view, they add up to one of the most fundamental objectives of unionism: the enhancement of human dignity and self-fulfillment at work.

For decades, we have heard corporation executives exclaim: "Our workers are our most valuable resource." Quality-of-worklife programs are designed to make that slogan a reality. How? By altering the autocratic climate of the workplace and providing workers, through their union, with the opportunity to participate meaningfully in the decisionmaking process at the workplace; by focusing management's orientation toward concern for the needs and aspiration of the workers; and by creating an atmosphere of cooperative effort between union and management to achieve the above noted objective. □

The quality-of-worklife project at Bolivar: an assessment

BARRY A. MACY

The quality-of-worklife project[1] at Harman International Industries, Inc., in Bolivar, Tennessee, is a cooperative change effort between the company and the United Automobile Workers of America (UAW). The project is structured so that both parties can jointly determine and implement organizational change according to mutually agreed-upon principles. The objectives of the project are to improve employees, quality of worklife and enhance organizational effectiveness.

The explicit internal goals were identified as job security, job equity, worker humanization, and worker democracy. These were ambitious undertakings in 1973—ahead of their times in many respects—particularly because they were shared and agreed to by both labor and management. However, some of the objectives of the project have been reached and surpassed, while others have yet to be reached. Other outcomes and critical process events are discussed in an assessment study by Macy and others.[2]

According to the five intervention phases of the Bolivar experiment, each composed of 11 months beginning with the baseline phase through plant-wide experimentation to coincide with the change program, the following changes were measured:

Job security. More jobs were created, as the hourly employment level rose 55 percent to 839. Once the program was underway, the cooperative union-management climate stimulated an effort to develop a joint bid on a particular product, and the company and the UAW established joint efficiency rates with the goals of increasing employees' quality of worklife and improving job security. Ultimately, this venture saved 70 jobs. Voluntary turnover rates declined by 72 percent, while involuntary turnover (discharges, retirements, and so forth) rates decreased by 95 percent.

Health and working conditions. Accident rates, as defined by the Occupational Safety and Health Administration, declined 60 percent, while minor accidents decreased 20 percent even with the presence of many new and inexperienced employees. Rates of short-term absences due to sickness declined 16 percent. However, not all of the changes were favorable, as the rate of minor illnesses rose 71 percent and the rate of medical leaves increased 19 percent. (Perceptions of Bolivar employees' health appear later in this report.)

Financial security. The average hourly rate remained constant and the wage rates relative to area standards did not change (during this time, the wage rates for the whole country did not increase relative to real wages). The fringe benefit package increased by a small amount. Proposals for the introduction of a gain-sharing compensation plan (a negotiable issue) were discussed but none was adopted.

Job security based on organizational performance. Daily output per hourly-paid employee, adjusted for inflation, rose 23 percent. Two other measures of productivity—efficiency and standard performance—verify this positive change in plant performance. On the product side of the financial ledger, net product reject cost rates declined 39 percent, while the rate of customer returns decreased by 47 percent. Once again, not all was positive

---

Barry A. Macy is director of The Texas Center for Productivity and Quality of Work Life and associate professor of Organizational Behavior at the College of Business Administration, Texas Tech University.

as the rate of manufacturing supplies used rose 22 percent and the rate of machine downtime increased slightly. What is so striking about productivity and product quality at the Harman International plant is the fact that both of these performance measures increased. Moreover, these measures have held positive and significant trends for approximately 3 years. Some of the gains are attributable to technological and capital inputs; however, many can be attributed to the cooperative labor-management change.

Cost-benefit. The cost-benefit calculations for the project reflect the program costs and benefits per hourly-paid employee per phase, summed over 55 months. The results show a net discounted benefit per hourly-paid employee to the company of more than $3,000. There are multiple reasons for this net savings, but nevertheless, the plant improved its performance through a combination of forces, including the cooperative quality-of-worklife program.

In summary, the evidence shows that because of the quality-of-worklife program, jobs objectively became more secure; productivity and product quality rose; accidents decreased at a faster rate than their industry average; minor accidents declined while minor illnesses rose; short-term absences due to sickness declined; manufacturing supplies and machine downtime increased; and employee earnings held steady. Also, grievances decreased 51 percent and absences due to lack of work decreased 94 percent.

Table 1. Assessment of quality-of-worklife indicators and work environment characteristics

Gains	No change	Losses
	QUALITY OF WORKLIFE	
Less alienation	Job satisfaction	More reports of physical stress symptoms
Treated in a more personal way	Job offers opportunity for personal growth	More reports of psychological stress symptoms
Job involved more use of, or higher level, skills	Working conditions	Less satisfaction with pay level
	Work equity	
Job is more secure	Fringe benefits	Less satisfaction with pay equity
	WORK ENVIRONMENT	
Supervisors more participative	Role conflict	Supervisors are less work-facilitating, supportive, and respectful
	Job variety	
More work-group participation	Supervisory closeness, favoritism, and feedback	
More employee influence over task-related decisions	Work-group feedback	Less satisfaction with work group
More adequate work resources	Employee influence over work-schedule decisions	Less association between work performance and reward received (3 indicators)
More work improvement ideas provided by employees	Association between job security and intrinsic motivation with work performance	Less job feedback
	General organizational climate	
	Work improvement suggestions	

NOTE: Assessment based on 85 matched UAW members.

These positive behavioral and organizational performance gains seem to have had some practical implications for both the company and the union in their contractual process. The company's 1976 contract with the UAW was signed earlier than ever before and benefited both the company and the union membership by reducing the need for higher product inventories while maintaining the same employment level. These bargaining sessions, as contrasted to previous ones, were accomplished and concluded in a mutual atmosphere of cordiality, creativity, and trust. Absent was the win-lose philosophy and counterthreats that often accompany traditional labor-management bargaining. This is not to indicate that the adversary relationship between the UAW and Harman International Industries has vanished. It has not! The union still grieves contract issues; however, the spirit or climate in which grievances are handled has improved.

Generally, the behavioral and performance findings were positive, while the attitudinal indicators showed mixed results. Thirteen indicators of the quality of worklife and 24 measures of job and work environment characteristics known to be associated with higher quality of worklife are assessed in table 1. (The data refer only to UAW members; however, these indicators represent fairly well the different types of employees surveyed at the Bolivar plant.) Some of the gains have been offset by losses or no change. It must be remembered, however, that over the extended period studied, there were some unmeasured changes in the employees' level of aspirations and expectations. These changes in expectations and aspirations were enhanced by the quality-of-worklife program and the later conditions were probably judged more critically than the earlier conditions. When asked a series of questions pertaining to the goals and outcomes of the quality-of-worklife program, the employees responded generally with positive opinions about the impact, the desirability of the program, the effectiveness of the union-management relationships, and the ability of the UAW to represent membership concerns. For example, 60 percent found the program to be desirable; a majority found the joint union-management committee responsible for designing and implementing the program to be effective without domination from either party; and 67 percent indicated that the program strengthened the local union. In addition, 90 percent of the UAW membership were satisfied with the local union in 1976, compared with 78 percent in 1973. This is substantially higher than the satisfaction level of a national sample of blue-collar union members with their union during this period.[3] Moreover, union membership at the Bolivar plant has increased from 65 percent to more than 90 percent, and 100 percent of the union membership responded affirmatively when asked: "If there were an election today on whether or not the union should be kept at Harman International Industries, how would you vote?"

These results and other outcomes not reported here[4] seem to indicate that the union members perfer to use joint union-management programs to deal with quality of worklife and other important domains of their life at work. Recently, many other reports and studies[5] have indicated similar trends and like results with other union members. One trend seems very clear. The time is ripe for the U.S. industrial relations system to seriously consider cooperative union-management programs along with their traditional contractual and collective bargaining structures and processes. ☐

FOOTNOTES

[1] The project was independently assessed during 1972–79. The behavioral and performance outcomes were evaluated for 55 consecutive months during 1972–76. Support for this article was provided by the Ford Foundation and the Economic Development Administration, U.S. Department of Commerce.

Special Labor Force Reports–Summaries

Trends in educational attainment among workers in the 1970's

ANNE MCDOUGALL YOUNG

The proportion of working men and women with some college education increased steadily throughout the 1970's. By March 1979, 36 percent of all workers age 18 and over had completed at least 1 year of college, up from 26 percent 9 years earlier; about half of those with some college education had completed at least 4 years. The proportion of workers whose formal education had ended with high school graduation remained close to 40 percent throughout the decade, but the percent who had not completed high school declined considerably (table 1).[1]

Labor force participation. During the 1970's, the proportion of men participating in the labor force continued to fall. The decline was steepest for those with less than a high school education—from 73 percent in 1970 to 62 percent in 1979 (table 2). As might be expected, the decrease was greatest among dropouts 55 years old and over, who were least equipped educationally to compete in an increasingly technological and specialized labor market, and who, in many cases, qualified for social security or other retirement benefits. But even the labor force participation rates of males with a high school education or better, with the exception of those under 25, tended to edge downward over the decade.

In contrast to the situation for men, women with at least a high school education sharply increased their labor force participation during the 1970's. When ranked by age and years of school completed, the greatest surge occurred among those 25 to 34 with 1 to 3 years of college. Their labor force participation rate rose from 45 percent to 67 percent between March 1970 and March 1979. The pattern of rising labor force participation also extended to younger women who had dropped out of high school and who lacked job market experience as well.

The increasing labor force participation of women is related, in part, to the growing proportion of women with post-secondary education. By 1979, 34 percent of female workers had completed at least 1 year of college, compared with 24 percent in 1970. Over the same 9-year period, the number of women awarded associate degrees[2] nearly tripled, while the number of men receiving such degrees almost doubled.[3] As a result, women accounted for 50 percent of all associate degrees in 1979—up from 42 percent in 1970—and nearly equaled men in the proportion completing vocationally oriented science and engineering-related courses. The availability of occupational training at community colleges, as well as the convenient locations of such schools, have particularly benefited women, both recent high school graduates and older workers, by providing an opportunity to acquire

para-professional training for a wide variety of jobs.

Historically, college graduates have maintained relatively high labor force participation rates. As expected, rates for male graduates under age 55 remained high during the 1970's. Among female graduates, however, the growth in labor force participation rates was truly startling. The rate increased nearly 20 percentage points for graduates age 25 to 34 and by almost as much among those 35 to 44. Apparently, women college graduates have become more determined to use their skills in the labor market.

Women have been keeping up with men in terms of the proportion receiving a bachelor's degree, but still lag far behind in the acquisition of advanced degrees.[4] However, women continued to increase, at least slightly, their percentage representation among graduates in the various fields at all degree levels over the decade. Among bachelor's and master's degree recipients, representation increased most in those fields which had relatively few female graduates in the early 1970's. Among Ph.D recipients, the opposite relationship prevailed; the smaller the representation of women early in the decade, the smaller the percentage-point gain. In the words of one observer, "It may be conjectured that the complex sociocultural forces which are influencing women to enter nontraditional fields of study have not been operating long enough to be manifest at the highest degree levels. If this is so, then the trends already observed at the bachelor's and master's degree levels may soon be evident at the doctoral degree level."[5]

Unemployment. In March 1980, unemployment rates continued their traditional relationship to years of school completed; that is, the more years of education, the lower the unemployment rate (table 2). As might be expected, older workers were less likely than younger ones to be unemployed, regardless of their educational attainment. Black workers had higher unemployment rates than whites at every level of educational attainment. The difference was greatest for men who had completed only 1 to 3 years of high school, but black unemployment rates were double those of whites even among college graduates.

Occupations. The steady rise in average years of school completed by American workers has led to a substantial upward shift in the educational levels of workers in major occupational groups. College graduates dominated high-level white-collar occupations to a much greater extent in 1979 than in 1970. Over the same period, the proportion of blue-collar workers who were at least high school graduates also increased (table 3).

During the 1970's, college graduates filled an increasing proportion of professional and technical jobs formerly held by persons with only a high school diploma. The proportion of workers in professional and technical occupations who were college graduates grew from 61 to 71 percent for men and from 54 to 63 percent for women over the decade. Similarly, the proportion of managers who had either attended or graduated from college rose, while the proportion of such positions held by high school dropouts declined sharply. The latter change also reflected the retirement from the labor force of older workers who had attained positions of responsibility many years earlier.

The proportion of sales and clerical workers of both sexes who were college graduates almost doubled over the decade, while the percentage with fewer than 12 years of high school fell by more than half. Among male clerical workers, for example, the proportion without a high school diploma dropped from 30 to 13 percent, and among women, from 20 to 8 percent. Computerization of business transactions and other changes in office practices have obviously generated a need for more highly trained workers. The increase in the supply of such workers thus coincided with, and made possible, the use of more complex information processing techniques. The upgrading of the educational level of workers was apparent among other occupations as well. For example, in 1970, more than half of all blue-collar and service workers had completed fewer than 4 years of high school, but by 1979, 44 percent were high school graduates and the proportion with 1 or more years of college had doubled.

Over the decade, the content of many jobs has changed drastically because of technological advances. Nonetheless, the data appear to indicate that many better educated persons are entering jobs for which formal educational requirements in previous years were far lower. This trend could have negative repercussions. "To the extent that growing numbers of workers may perceive themselves to be overqualified for their jobs," writes one analyst, "declining job satisfaction may reflect a worsening match between workers' educational attainment and the actual requirements of the work

they perform,"[6] and emerge as a major problem for workers and employers in the 1980's. □

FOOTNOTES

[1] Data for this report are based primarily on special annual tabulations of information obtained through the Current Population Survey, conducted monthly for the Bureau of Labor Statistics by the Bureau of the Census. The data relate to the civilian noninstitutional population 16 years and over (unless otherwise specified) in the week ending Mar. 17, 1979. Because the estimates are based on a sample, they may differ from the figures that would have been obtained from a complete census. Sampling variability may be relatively large in cases where the numbers are small. Small estimates, or small differences between estimates, should be interpreted with caution. This report is the latest in a series on this subject. The most recent was published in the *Monthly Labor Review*, February 1979, pp. 54–58, and reprinted as Special Labor Force Report 225. Data on the educational attainment of the population are published by the Bureau of the Census in *Current Population Reports*, Series P-20.

[2] A degree awarded for completion of programs below the baccalaureate level, based on fewer than 4 years of work beyond high school in an accredited institution of higher learning.

A note on communications

The *Monthly Labor Review* welcomes communications that supplement, challenge, or expand on research published in its pages. To be considered for publication, communications should be factual and analytical, not polemical in tone. Communications should be addressed to the Editor-in-Chief, *Monthly Labor Review*, Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

Research Summaries

Wage gains in 1979 offset by inflation

JOAN D. BORUM

Although workers received large pay gains in 1979, prices rose at an even higher rate and their purchasing power fell. Many of the key statistical series discussed in this article posted smaller money wage increases in 1979 than in 1978. And, for the first time since 1974, they all showed declines when adjusted for inflation. A number of forces tempered 1979 wage increases, including the voluntary wage and price standards announced by President Carter in late 1978, a slowdown in employment growth, and a decline in productivity.

Compensation measures

The Bureau publishes several measures of changes in employee compensation.[1] Some cover rates of pay, others study workers' earnings. Depending on the series, the data may reflect payments for benefits as well as wages and may show the influence of weekly hours and Federal tax rates. Data usually are available in both current dollars and 1967 dollars. A brief review of key measures in 1979 follows. Earnings data reflect percent changes from December to December; average hourly compensation data reflect percent changes from fourth quarter to fourth quarter.

Gross average hourly earnings, one of the basic measures, covers production and nonsupervisory workers in the private nonfarm sector. In 1979, these earnings rose 7.9 percent, considerably less than the 9.4-percent rise in 1978. (See table 1.) When adjusted for inflation, real earnings were down by 4.8 percent, compared with a 0.3-percent increase in 1978.

The *Hourly Earnings Index* is widely used for measuring the general movement in wages because it eliminates from the gross hourly earnings the effects of interindustry employment shifts (that is, changes in the relative number of workers in high-paying and low-paying industries) and overtime fluctuations in manufacturing. This index increased 8.4 percent—about the same as in 1978. However, after adjustment for price increases, the index was down 4.4 percent, compared with a 0.5-percent decrease in 1978.

Average weekly earnings reflect both gross hourly earnings and the number of weekly hours. Because of a decline in weekly hours during 1979, average weekly earnings rose at a 7.6-percent rate, slightly less than gross average hourly earnings. Real average weekly earnings declined at a 5.1-percent rate, after rising slightly (0.1 percent) in the previous year.

Spendable weekly earnings measure weekly earnings after deductions of Federal social security and income taxes for a worker earning the average weekly pay, taxed at the rates applicable to a married worker with three dependents. This series posted a 7.6-percent gain in 1979, considerably more than in 1978 (5.7 percent). When adjusted for inflation, spendable weekly earnings were down 5.1 percent, a steeper drop than in 1978 (−3.1). Unlike other earnings measures, this series was affected by an increase in social security taxes. The 1979 tax paid by employees (and matched by their employers) was 6.13 percent of the first $22,900 of annual earnings; in 1978, the tax was 6.05 percent of the first $17,700 of earnings. The series was also influenced by revisions in the Federal income tax laws.

[1] Changes are based on seasonally adjusted data and reflect fourth quarter to fourth quarter change for average hourly compensation and December to December change for other measures.

[2] Covers production and nonsupervisory workers in the private nonfarm economy.

[3] Covers all persons in the private business sector.

Joan D. Borum is an economist in the Office of Wages and Industrial Relations, Bureau of Labor Statistics.

cludes wages and salaries plus employer contributions for social insurance and private benefit plans.[2] Hourly compensation for all persons in the private business sector increased 9.2 percent; for those in the private nonfarm business sector, 9.0 percent; and in manufacturing, 9.2 percent. Comparable changes in 1978 were 9.1, 9.1 and 8.7 percent. Although hourly compensation rose substantially in the private business sector, productivity—output per hour of labor input—fell 1.7 percent. As a result, labor costs per unit of output rose even more rapidly than hourly compensation.

The *Employment Cost Index*, a relatively new series, provides a more refined measure of change in the "price" of labor. Covering both supervisory and nonsupervisory workers, this series measures changes in pay rates of a standardized mix of labor services. It is, therefore, unaffected by shifts of workers among occupations, firms, and industries. Data currently available pertain to wage and salary rates in the private nonfarm economy, excluding households, as approximated by straight-time hourly earnings.

In 1979, overall pay increases, as measured by the index, averaged 8.7 percent, up from 7.7 percent in 1978. (See table 2.) Pay in manufacturing was up 8.6 percent, nearly the same as in nonmanufacturing (8.8 percent). Among industries, pay increases ranged from 7.2 percent in construction to 13.2 percent in finance, insurance, and real estate—where compensation is largely influenced by fluctuations in commission earnings for sales workers. Among occupational classifications blue-collar workers received the highest 1979 pay increase, averaging 9.0 percent, followed by white-collar workers (8.6 percent), and service workers (7.2 percent). As in previous years, union workers received larger increases than nonunion workers. The differential can be attributed largely to wage increases in manufacturing where pay advanced 9.4 percent for union workers, compared with a 7.9-percent increase for nonunion workers.

Wage changes under major labor contracts

Data on wage changes in major collective bargaining units are restricted to bargaining units covering 1,000 workers or more in the private nonfarm sector. About 1 worker in 10 in the civilian labor force is covered by a major bargaining agreement. The agreements are usually in key industries and often set wage patterns for other establishments. Two basic types of data are available—data limited to contract settlements negotiated in the current period and all general wage changes put into effect in the period.

[1] Not available.

NOTE: The statistics are percent changes in straight-time average hourly earnings over the period indicated. They are not annualized, nor are they adjusted for seasonal influences.

Negotiated wage settlements affect a limited number of workers each year, but generally are reflective of current economic conditions and, because they usually cover 2 or 3 year periods, tend to influence wage increases in the following years. New contracts negotiated during 1979 provided for average first-year wage gains of 7.4 percent, the lowest since 1973. Annual wage adjustments over the life of the contracts averaged 6.0 percent, less than in any year since 1973, except 1977. (See table 3.)

In bargaining units with 5,000 workers or more, 1979 wage and benefit adjustments averaged 9.0 percent in the first contract year and 6.6 percent annually over the life of the agreement, compared with 8.3 and 6.3 percent in 1978.

About 58 percent of the workers covered by contracts negotiated in 1979 had cost-of-living adjustment (COLA) provisions in their agreements (37 percent in 1978), and most of these workers also had escalator provisions in their prior agreements. The existence of COLA clauses influences the size and the duration of settlements. (However, actual COLA increases are not included in the data presented here.) Agreements without automatic escalator provisions usually specify higher annual rates of change over the contract life. In units with 1,000 workers or more, 1979 contracts without COLA clauses specified an average annual wage increase of 8.0 percent; those with COLA's averaged 4.6 percent.

Agreements with COLA provisions are generally for a longer duration than those without escalator clauses. In 1979, the average duration for settlements with COLA

Table 3. Percent change in wages and wages and benefits in major collective bargaining agreements, 1974–79

Measure	1974	1975	1976	1977	1978	1979
Settlements:[1]

Total effective wage-rate adjustment	9.4	8.7	8.1	8.0	3.2	9.1
Adjustment resulting from:						
Current settlement	4.8	2.8	3.2	3.0	2.0	3.0
Prior settlement	2.6	3.7	3.2	3.2	3.7	3.0
Escalator provision	1.9	2.2	1.6	1.7	2.4	3.1

[1] Data exclude possible increases under escalator provisions, except for minimum increases guaranteed by the contract.

NOTE: Data relate to private nonfarm agreements.

was 35.9 months, 6 months longer than those without such clauses.

Effective wage-rate changes are more comprehensive than the settlement data and are more comparable to the earnings measures. This measure comprises all changes put into effect in a given period, including gains won in current settlements, increases negotiated in earlier years (deferred changes), and payments triggered by automatic cost-of-living escalator clauses. The size of each type of increase and the number of workers affected determine the total effective adjustment. Although the 9.1-percent average adjustment in 1979 for 9.3 million production and nonsupervisory workers was the highest since the 9.4-percent increase in 1974, it was considerably less than the 13.4-percent rise in prices (as measured by the Consumer Price Index for Urban Wage Earners and Clerical Workers—CPI-W). This is the second consecutive year in which wage changes in bargaining units averaged less than the change in prices.

The following tabulation compares the percent increase in the Consumer Price Index for Urban Wage Earners and Clerical Workers with wage changes in major collective bargaining units:

	CPI	*Total effective adjustment*	*Average escalator increase*
1975	7.0	8.7	4.8
1976	4.8	8.1	3.5
1977	6.8	8.0	3.9
1978	9.0	8.2	5.0
1979	13.4	9.1	6.8

The current settlement component of the effective-change measure is normally the largest of the three components in terms of the size of increase. During 1979, 3.5 million workers received increases averaging 7.9 percent as a result of settlements during the year. When prorated over the 9.3 million workers in the bargaining universe, this accounted for 3.0 percentage points of the total adjustment. (See table 3.)

The deferred component is more influential in light bargaining years, when fewer workers are covered by settlements and more receive deferred wage increases. In 1979, 5.5 million workers had deferred increases averaging 5.1 percent, accounting for 3.0 percentage points of the total effective adjustments.

Although a smaller portion of workers under major agreements received increases from COLA (44 percent, compared with 48 percent in 1978), the average size of their increases was larger (6.8 percent compared with 5.0). Prorated over all workers in major bargaining units, the average escalator adjustment was 3.1 percent. Interestingly, both the size of the average escalator adjustment and its share of the total adjustment were higher in 1979 than in any year since data became available in 1968.

The size of cost-of-living adjustments reflects the type of COLA formula, the timing of COLA reviews, and possible "caps" or limits on increases. In 1979, workers receiving COLA increases under major agreements recovered an average 51 percent of the rise in consumer prices. The most common formula, calling for a 1-cent an-hour increase for each 0.3-point rise in the CPI, affected about 2.1 million workers.[3]

In 1979, a heavy bargaining year, 3.5 million workers negotiated new contracts. The transportation equipment manufacturing industry accounted for about one-fifth of the total; the transportation industry accounted for another one-fifth; and many of the remaining workers were in the apparel, construction, electrical equipment, food manufacturing, and retail food store industries. More than 3.7 million workers are covered by contracts either expiring or permitting wage reopenings in 1980, another heavy bargaining year.[4] Key agreements to be negotiated are in the petroleum refining, construction, steel, telephone, and aerospace industries. Although the size of new settlements and the effective adjustments to be implemented cannot be predicted, it is known that 4.9 million workers are scheduled to receive deferred increases averaging 5.1 percent and that cost-of-living reviews are scheduled for 3.6 million workers.[5] □

[2] Except for nonfinancial corporations in which there are no self-

employed, data also include an estimate of wages, salaries, and supplemental payments for the self-employed.

[3] For additional analysis of current escalator coverage and provisions, see Edward Wasilewski, "Scheduled wage increases and escalator provisions in 1980," *Monthly Labor Review*, January 1980, pp. 9–13.

[4] For a more detailed discussion of the collective bargaining schedule for 1980, see Mary A. Andrews and Winston Tillery, "Heavy bargaining again in 1980," *Monthly Labor Review*, December 1979, pp. 20–28.

[5] The remaining 1.1 million workers are under clauses that do not provide for a review in 1980, primarily in contracts scheduled to expire during the year.

Working wives reduce inequality in distribution of family earnings

FRANCIS W. HORVATH

Past studies have shown that working wives move the aggregate family earnings distribution towards greater equality.[1] That is, the distribution of *family* earnings has shown more relative equality than the distribution of *husbands'* earnings. This effect occurred, in part, because the wives entered the labor force in greater numbers from families with lower than average earnings. Labor force participation of wives had been found to be negatively related to the earnings of their husbands.[2]

In recent years, more wives from higher income families have been entering the labor force.[3] In the absence of other changes that would affect the earnings distribution of families (for example, changes in the participation rate or earnings of wives of low earners), an increase in the labor force participation rate of wives of high earners would increase family earnings inequality *regardless* of the level of wives' earnings. This occurs because families already near the top of the earnings distribution with only the husband working will move farther up the distribution with any additional earnings of the wife. In addition, if these wives display earnings which are higher than average for women, the increase in inequality would even be greater.[4] Such a positive relationship between earnings of husbands and wives can be expected, given the observed tendency of men and women to marry persons with socioeconomic characteristics and hence earnings capacities similar to their own. While the extent to which earnings capacities are translated into current earnings is tempered by a variety of institutional and personal factors, including the individual's lifetime labor force participation and the degree of discrimination in the labor market, an emerging positive relationship between observed earnings of husbands and wives will tend to increase inequality in the family earnings distribution.

The question is: is the distribution of the combined earnings of husbands and wives still more equal than the distribution of earnings of husbands alone? Ideally, the appropriate test would involve a comparison of standardized inequality measures over time. The test here involves a single point in time. Nevertheless, it is possible to highlight the increasing influence of working wives on earnings inequality by contrasting two work experience groupings: all husband-wife families and families with both spouses working year round, full time. If two-earner families continue to increase as a proportion of husband and wife families, a comparison of earnings inequality between couples who each work full time and overall families may provide some indication of future trends.

The difference between the distribution of husbands' earnings and the distribution of the combined earnings of husbands and wives can be accounted for completely by three factors: the distributions of wives' earnings, husbands' earnings, and the interrelationship between husbands' and wives' earnings. The impact of working wives' earnings will be reflected by a difference in the measures of inequality between the earnings distributions for husbands and the combined husband-wife earnings distribution.

To examine inequality, we employ a method similar to that used by Jacob Mincer in *Schooling, Experience, and Earnings*.[5] Simply stated, inequality is measured by the size of the standard deviation of the natural logarithm of earnings. The lower this measure is, the more equal is the distribution of earnings. (See appendix.)

The data used here are for 1977 and are based on a subsample of the Current Population Survey of March 1978. The sample included only husband-wife families who were living together during March 1978. Excluded were families with husbands who were self employed, farmers, students, or over 64 years of age—persons whose earnings are known to vary widely. Because the log of zero is undefined, husbands with no earnings and families with zero total earnings also were omitted.

Table 1 shows the mean values for husbands' earnings, husbands' and wives' earnings, the respective standard deviations and the standard deviations of the natural logarithms of earnings. The data are displayed by age of the husband and two work experience classifications. The first set of data shows all families in the sample regardless of work experience; the second grouping contains only families in which both husband and wife worked year round, full time.

The difference in inequality between husbands and husbands and wives in the first set is related to both the labor force participation of wives and earnings levels. The second grouping, however, contains no variation in

---

[1] Both spouses employed year round, full time.

labor force participation. Here, the impact of the presumed positive correlation of husbands' and wives' earnings may contribute to inequality of earnings because there is no participation-income relationship as in the first set.

The main issue is the comparison of the standard deviations of the logarithms of earnings of the husbands and the combined earnings of husbands and wives. (Smaller values indicate lesser relative inequality.) In all age groups, the combined earnings distribution shows greater relative equality than the husbands' earnings distribution alone. This was true even for families in which both husbands and wives worked year round in full-time jobs. In fact, the drop in relative inequality appears to be greater for working families than for the overall groups. That is, in families with both spouses working full time, where observed earnings more closely approximate potentials, the equalizing effect of working wives was more apparent.

This finding becomes more intuitive after consideration of some of the facts which underlie the data. The earnings distribution of full-time, year-round working wives tends to be highly concentrated about its mean. Until this earnings distribution of wives begins to spread out, the impact on the family earnings distribution is roughly equivalent to the addition of a constant amount to each husband's earnings, which causes relative inequality to fall.

Despite larger numbers of wives from higher income families in the labor force, working wives still tend to be an equalizing force on the distribution of family earnings. The combined earnings distribution, whether for all husband-wife families or husband-wife families in which both spouses work full time year round, shows more equality than the husbands' earnings distribution. ☐

Miller, *Income Distribution in the United States* (Washington, Government Printing Office, 1966), and James Sweet, "The employment of wives and the inequality of family income", *Proceedings of the American Statistical Association*, 1971. A more complete discussion of some of the issues presented here appeared in James P. Smith, "The Distribution of Family Earnings", *Journal of Political Economy*, 1979, Vol. 87, No. 5, pp. S163–92. That study, which used the Census Public Use Samples and the Michigan Income Dynamics Survey Panel, comes to conclusions analogous to those here.

[5] Mincer compared the inequality of the husbands' earnings distribution to the inequality of the total family income distribution. The use of the combined distributions of husbands' and wives' earnings differs slightly from Mincer's method. We chose this procedure because the possibility exists that family income may include other incomes besides those of the earnings of husbands and wives.

APPENDIX: Variance of the natural logarithm as a measure of inequality

The variance (or standard deviation) of the natural logarithm (s^2) is one of the most frequently used measures of inequality. The larger the variance, the greater the inequality evidenced in the data. If each of the observations on earnings in a data set is increased by the same percentage, the value of the variance of the logs remains the same. However, if each of the observations is increased by a constant amount, the variance of the logs will diminish. This occurs because a fixed amount will represent a greater percentage increase for those at the bottom of the earnings distribution than those at the top. While the absolute spread between the bottom and the top of the distribution remains the same size, inequality has lessened since the spread is around a higher mean.

The relationship between husbands' earnings and combined earnings of husbands and wives is not completely obvious, and in moving from the absolute standard deviations to the log measures, some pitfalls in interpretation can arise. In absolute terms, the relationship between husbands' earnings and combined earnings follows the general form of the variance of a sum. If

$$E_T = E_H + E_W$$

where E_T is combined earnings, E_H earnings of the husband, and E_W earnings of the wife, then

$$\mathrm{Var}\,(E_T) = \mathrm{Var}\,(E_H) + \mathrm{Var}\,(E_W) + 2\,\mathrm{Cov}(E_H, E_W).$$

The variance of the total must be greater than the variance of the husbands' and wives' earnings unless the covariance between husband and wife earnings is negative and large enough to overwhelm the variance of wives' earnings.

The relationship between the relative values is not as simple. Consider the following:

$$E_T = E_H + E_W$$

which we may write as:

$$E_T = E_H(1 + E_W/E_H) = E_H(1 + R_F)$$

where R_F is the ratio of wife's to husband's earnings. Taking the logarithm of this product yields:

$$\ln E_T = \ln E_H + \ln(1 + R_F)$$

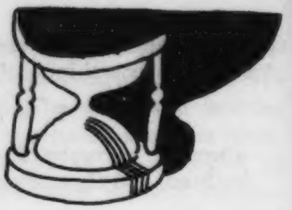
on which we may apply the variance operator as above:

$$\mathrm{Var}(\ln E_T) = \mathrm{Var}(\ln E_H) + \mathrm{Var}(\ln(1 + R_F)) + 2\,\mathrm{Cov}(\ln E_H, \ln(1 + R_F))$$

It should be noted that it is possible for absolute earnings of husbands and wives to be positively related ($\mathrm{Cov}(E_H, E_W) > 0$), and yet to observe a drop in relative inequality ($\mathrm{Var}\ \ln E_T < \mathrm{Var}\ \ln E_H$).

Indeed, among families in which both husband and wife work full time year round, a positive relationship was found between husband and wife earnings (not shown here) together with a large drop in relative inequality. While a positive relation between husbands' and wives' earnings will tend to reduce the equalizing effect of working women on inequality, it is only one part of the total effect. The other consequence is to reduce the variation in $\ln(1 + R_F)$, which may be closely identified with the ratio of wives' to husbands' earnings. As wives enter the full-time labor force, the bottom end of the distribution (those with a ratio of zero) drops in size, and the total variation of $\ln(1 + R_F)$ diminishes.

Major Agreements Expiring Next Month



This list of collective bargaining agreements expiring in August is based on contracts on file in the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more.

Employer and location	Industry	Union[1]	Number of workers
Air Conditioning and Refrigeration Contractors Association of Southern California (California)	Construction	Plumbers	1,200
Al Tech Specialty Steel Corp. (Dunkirk & Watervliet, N.Y.)	Primary metals	Steelworkers	2,000
Alabama Power Co. (Alabama)	Utilities	Electrical Workers (IBEW)	3,500
Allegheny Ludlum Industries, Inc. (Interstate)	Primary metals	Steelworkers	5,800
American Telephone and Telegraph Co., Long Lines Department (Interstate)	Communication	Communications Workers	22,600
Armco, Inc. (Interstate)	Primary metals	Steelworkers	12,100
Babcock & Wilcock Co., Tubular Products Division (Beaver Falls, Pa.)	Primary metals	Steelworkers	5,050
Bell Telephone Co. of Pennsylvania:			
Commercial and Marketing Departments	Communication	Pennsylvania Telephone Guild (Ind.)	2,700
Comptrollers and Treasurers Department	Communication	Federation of Telephone Workers of Pennsylvania (Ind.)	1,300
Plant Department	Communication	Federation of Telephone Workers of Pennsylvania (Ind.)	12,150
Traffic Department	Communication	Electrical Workers (IBEW)	5,250
Bell Telephone Laboratories, Inc. (Illinois and New Jersey)	Electrical products	Communications Workers	1,450
Bethlehem Steel Corp. (Interstate)	Primary metals	Steelworkers	50,000
Cameron Iron Works, Inc. (Texas)	Machinery	Machinists	3,300
CF&I Steel Corp. (Pueblo, Colo.)	Primary metals	Steelworkers	6,000
Chesapeake and Potomac Telephone Co. (Interstate)	Communication	Communications Workers	31,750
Cincinnati Bell, Inc. (Ohio and Kentucky)	Communication	Communications Workers	3,500
Cleveland Cliffs Iron Co. (Interstate)	Mining	Steelworkers	3,800
Cleveland Food Industry Committee, 2 Agreements (Interstate)	Retail trade	Food and Commercial Workers	11,900
Consumers Power Co. (Michigan)	Utilities	Utility Workers	4,500
Cooper Industries, Inc., Cooper Energy Services Division (Grove City, Pa.)	Machinery	Steelworkers	1,100
Copperweld Steel Co. (Warren, Ohio)	Primary metals	Steelworkers	1,950
Crucible, Inc. (New York and Pennsylvania)	Primary metals	Steelworkers	6,300

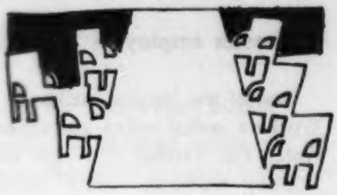
Developments in Industrial Relations



AFL-CIO remains committed to 'national accord'

At its spring meeting, the Executive Council of the AFL-CIO contended that President Carter's efforts to counter inflation by cutting the Federal budget had resulted in a "budget that was 'balanced' in dollars, but which was unbalanced in human terms, creating increased joblessness and needless suffering and hardship for millions." The Council asserted that the President's actions amounted to abandonment of some of the principles and commitments of the "national accord" between organized labor and the Administration on stemming inflation. However, the 35-member Council reaffirmed the AFL-CIO's commitment to the accord; the only dissenting vote was cast by Rubber Workers president Peter Bommarito.

Federation President Lane Kirkland said there was no other choice because "we're here to maintain representational relations with the institutions of policy and of power and of government in this country. . . . The game may be rigged, but it's the only game in town."

Turning to the issue of wage negotiations, Kirkland said he would "advise our members to engage in vigorous collective bargaining in representing their members as forcefully as they can." Asked if this meant ignoring the current 7.5- to 9.5-percent annual pay guideline first advocated by himself and the other members of the Pay Advisory Committee established in conjunction with the national accord, Kirkland replied that the voluntary pay program hadn't "repealed" Federal labor laws requiring union leaders to represent their members' best interests. However, he later softened his stance, saying that the pay standard is flexible enough to generally permit union negotiators to negotiate economic gains approaching those that could be won if there was no pay standard.

Master agreement covers Atlantic and Gulf ports

The International Longshoremen's Association and shipping associations along the Atlantic and Gulf Coasts tentatively agreed on the first master contract for all major ports, except New Orleans. In the past, a master agreement was reached for the major North Atlantic Coast ports which set the pattern for agreements in other Atlantic and Gulf Coast ports.

The agreement, subject to worker ratification after local port agreements have been reached, covers 45,000 workers. The agreement will be effective on the October 1, 1980, termination date of existing contracts. The early settlement on master terms was part of the parties' plan to permit the maximum possible time for settlement of difficult local port issues, such as guaranteed annual income plans, which vary from port to port and guarantee eligible ILA members specified numbers of hours of pay per year.

The new 3-year agreement provided for increases in the basic wage rate of $1.20 an hour on October 1, 1980 (the previous rate was $10.40) and on October 1, of 1981 and 1982. The current employer contribution to the pension funds of $2.25 an hour will increase by 25 cents in each year of the contract and the current contribution to the health and welfare funds of $1.50 an hour will increase by 17 cents in each of the first 2 contract years and 16 cents in the third year. Also, the contract permits the union to refuse to load and unload ships of ocean carriers which refuse to subscribe to the Job Security Program, which requires ocean carriers to pay uniform assessments, regardless of the port, into a common pool to meet shortfalls in local guaranteed annual income, pension, and health and welfare funds.

During the first bargaining sessions, which began in February, the parties reviewed the legal status of the Rules on Containers—a key contract item—which have been in litigation before the National Labor Relations Board and the Federal courts for nearly 7 years. The rules were developed over the years to preserve specified container cargo handling work for ILA members. In 1977, an adverse ruling on the legality of the container clause precipitated strikes aimed at containerships. No such problem was expected in 1980 because the Supreme Court is scheduled to review the rules. However, the union can cancel the agreement on 60 days' notice after December 1, 1980, if the Supreme Court strikes down the Rules on Containers.

"Developments in Industrial Relations" is prepared by George Ruben and other members of the staff of the Division of Trends in Employee Compensation, Bureau of Labor Statistics, and is largely based on information from secondary sources.

Harvester employees end 172-day strike

One of the longest strikes in the history of the Auto Workers ended when employees of International Harvester Co. ratified a 3-year contract. Throughout the 172-day walkout, which involved 35,000 workers in nine States, the chief issues were demands for changes in overtime work and job transfer provisions the company said were needed to reduce a labor cost imbalance with its competitors in the farm and construction equipment industry.

International Harvester did not gain its demand for the right to require employees to work overtime, but there were some changes in the voluntary approach to overtime. The company will be permitted to establish a pool of volunteers who will work the overtime, if enough regular employees refuse the work. If this pool is not adequate, additional volunteers will be available from a pool of laid-off employees who are not eligible for Supplemental Unemployment Benefits or have exhausted their benefits. The final source will be a pool of retirees who have volunteered to perform overtime work.

The company's demand that employee-initiated job transfers be limited to two a year was shifted from the national bargaining table to the local bargainers for resolution, resulting in some variation in the final provisions. Reportedly, most of the local agreements continue to permit employees to make an unlimited number of upward transfers in a year but limit the number of lateral and downward moves.

According to the union, the economic terms of the national contract meet or exceed the pattern established by the union with the International Harvester's competitors, such as Deere and Co.

Continued cutbacks in steel and auto industries

The depressed state of the steel industry was reflected in U.S. Steel Corp.'s announcement that its management employees will not receive a general salary increase in 1980. In the letter to the employees, distributed after U.S. Steel and other major basic producers settled with the Steelworkers for production and related workers (see *Monthly Labor Review*, June 1980, p. 57), the company indicated that funds had beenallocated for merit increases. The management employees are not represented by a union. U.S. Steel, like other steel producers, also was cutting back output and employment to counter the industry's problems, which, it says, stemmed from continuing increases in steel imports and production cuts by steel-using industries, such as construction and automobile manufacturing.

The continuing decline in sales of domestically manufactured automobiles and trucks was evident, as steel manufacturers announced some permanent plant closings as well as some short-term closings. About 300,000 workers were affected by layoffs or permanent job losses, and about 40,000 salaried jobs were expected to be eliminated by June. During the last sales slump, in 1974–75, fewer salaried employees were affected and virtually all of them were recalled when the slump ended. The latest announcement of white-collar job terminations came at the end of April, when General Motors Corp. said that it was reducing its worldwide staff of 180,000 salaried workers about 10 percent, on top of some 2,000 jobs it had eliminated earlier. Cuts in salaried jobs at Ford Motor Co. had reportedly totaled more than 6,000 in recent months and, at Chrysler Corp., more than 15,000 white-collar employees have been terminated since last fall.

The manufacturers also were making other moves to reduce labor costs. Ford Motor Co. ceased granting merit increases to its 70,000 salaried workers for at least the balance of 1980 and also ceased contributing to the workers' investment plan for an indefinite period. The 56,000 participants in the investment plan were permitted to invest a portion of their salary in Ford stock, with the company contributing 60 cents for each dollar. For 1979, Ford's contribution totaled $78 million.

New contract for General Telephone employees

More than 20,000 employees of General Telephone Co. of California are covered by a 3-year contract negotiated by the Communications Workers. It provides for a wage increase of 7 percent, retroactive to the March 5 termination date of the prior contract, and for increases of 2.5 percent in October 1980, 3 percent in March 1981, and 2.5 percent in March 1982. The agreement also establishes a wage escalator clause providing for increases of up to 6 percent in October 1981 and 6.5 percent in October 1982, calculated at the rate of 0.7 percent for each 1-percent rise in the BLS Consumer Price Index for Urban Wage Earners and Clerical Workers for the Los Angeles area during the preceding 12 months.

Benefit improvements included a fifth week of paid vacation after 25 years of service (beginning in 1982), a 12th annual paid holiday, and an increase in the annual pension rate to 1.35 (formerly 1.3 percent) percent of average annual preretirement earnings for each year of credited service.

Union president Glenn E. Watts said that the agreement was within the 7.5- to 9.5-percent guidelines for increases in employee compensation specified in President Carter's anti-inflation program. Watts, an alternate member of the President's Pay Advisory Committee, earlier had said that the Communications Workers would stay within the pay guidelines in its negotiations with the Bell telephone system companies to replace contracts expiring in August 1980 for more than 500,000 workers. General Telephone Co. of California is not part of the Bell system.

Workers gain access to medical records

Another development in the continuing effort to improve job safety and health occurred when the Department of Labor announced a new rule giving employees access to their on-the-job medical records. Effective August 21, employers must furnish medical records within 15 days after an employee requests them. The only information that can be withheld is that regarding a terminal illness or mental problems; such information will be furnished to a person chosen by the employee, who will decide if it is in the employee's best interest to see it.

Employers are also required to furnish medical records to unions representing the workers, if the workers give their consent. However, OSHA investigators can obtain the records without the prior consent of the employees. Another provision of the rule requires that medical records be kept for up to 30 years after an employee stops working.

OSHA officials indicated that the new rule will not require additional recordkeeping by employers. Eula Bingham, Assistant Secretary of Labor for Occupational Safety and Health, said that the regulation fulfills a basic right of workers—the right to know "what they are working with and its effect on them," vital information which previously has been "locked away in employers' files."

Jewelry Workers to merge with Service Workers

Delegates to the Jewelry Workers triennial convention voted to merge their 10,000-member union into the Service Employees union, which currently has about 625,000 members. Jewelry Workers President Leon Sverdlove said that the move will help in efforts to organize unrepresented workers in the industry. Under the merger, Jewelry Workers locals will retain their identity in a new jewelry division of the Service Employees union that will be headed by Sverdlove, who will also become a member of the Service Employees executive board.

In welcoming the Jewelry Workers, Service Employees President George Hardy assured them that there would be no change in the basic structure of their union, that his union had added 50,000 members in the past 10 years through mergers and affiliations and the incoming groups have been strengthened while upholding their autonomy and contracts.

Pattern-setting contract for Las Vegas hotels

More than 12,000 employees of resort hotels on "The Strip" in Las Vegas were affected by a 4-year settlement between the Nevada Resort Association and the Hotel and Restaurant Employees Union. The accord also was expected to influence settlements for a similar number of employees the union represents at other hotels in the city.

Skilled workers, who previously earned about $55 a shift, received a 75-cent-an-hour wage increase, retroactive to April 2, 70 cents in the second year, 60 cents in the third, and 55 cents in the fourth year. Semiskilled employees, who earned about $40 a shift, received increases of 60, 50, 40, and 40 cents an hour on the corresponding dates. Tipped employees, who are paid about $25 a shift by the hotels, received 40, 35, 35 and 30 cents increases. In addition, their guaranteed tip was increased to 16 percent from 15 percent, in the first contract year and to 17 percent in the second year.

Other wage provisions included a requirement that bell captains either have at least two of the three concessions they formerly operated returned to them or be paid an additional $30 a shift. The concessions are for show reservations, tours, and car rentals.

The association agreed to permit the international union to take over as the administrative agency for the health and welfare fund, which the union claimed could reduce operating costs and, thus, permit improved benefits.

Other changes included a 5-cent-an-hour increase (to 45 cents) in the employers' payment into the pension fund; a new provision permitting employees of either sex to take a leave of absence of 90 days to 1 year to rear an infant child; extension of sickness and accident benefits to cover childbearing; and a ban on using lie detectors for screening job applicants, except those who will be bonded.

Kansas City bakery workers get new contract

The Bakery, Confectionery and Tobacco Workers negotiated 2-year contracts with four Kansas City bakeries that the union said would set a pattern for 25,000 other bakery employees in eight midwestern States.

The accords provided for a 75-cent-an-hour wage increase in the first year, 70 cents in the second, and 3 cents to be used for special wage adjustments or benefit improvements.

Other provisions included accelerated progression to top pay rates for new employees; increased employer pension funding to permit an increase in the normal pension to $550 a month; a 2-year reduction in the service required for 4 weeks' vacation; and an increased employer contribution to maintain the level of health benefits for pensioners.

The four companies involved were ITT Continental Baking Co., Campbell-Taggert, Inc., Interstate Brands, and American Bakeries Co.

GPO female bookbinders awarded back pay

Federal District Judge Charles R. Richey awarded an estimated $6 million in back pay and $10 million in increased future earnings to 324 female bindery workers at the Government Printing Office to settle a class action job discrimination suit initiated in 1974. Richey, who had found the Federal facility guilty of the job discrimination in October 1979, held that 28 of the women had been paid only about 70 percent of the amount received by male bookbinders, despite the fact that they performed essentially the same operations. An attorney for the women said that they earned about $15,000 a year, compared with $25,000 for men. The women will receive the difference between the amounts for each year back to 1971.

The remaining 296 women will share an estimated $3 million that they would have earned had they not been denied an equal opportunity to be promoted to bookbinders.

Richey also awarded so-called "forward pay" to compensate the women for the continuing inequities in salaries, pensions, and other benefits that resulted from the unfair job policies. This pay will continue until 50 percent of all bookbinders positions are filled by women. Currently, only one of GPO's 106 bookbinders is a woman.

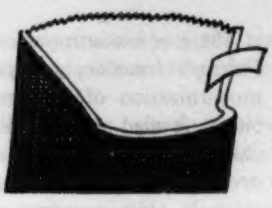
Residency requirement struck down

New York City's efforts to require its employees to live in the city suffered a blow when the State's highest court struck down the residency ordinance the city had enacted in 1978. The Court of Appeals ruling immediately applied only to the uniformed employees represented by the unions that had initiated the suit but city officials were studying the possibility that the principle might extend to nonuniformed employees. There was no immediate impact on the city's employees because the city had agreed not to enforce the ordinance pending the outcome of the court tests.

In a unanimous ruling, the court held, "While the structure and control of the municipal service departments in issue here may be considered of local concern within the meaning of municipal home rule, the residence of their members, unrelated to job performance or departmental organization, is a matter of statewide concern not subject to municipal home rule." More specifically, the court said that the ordinance was inconsistent with parts of the State's Public Officers Law, which prohibits residency requirements for firefighters and corrections officers in cities of a million or more population, of police officers in departments of 200 officers or more, and sanitation workers in cities of any size.

Mayor Edward Koch indicated that he would ask the State Legislature to pass a law allowing such a local requirement. The city had unsuccessfully sought such a State law a number of times before enacting the residency ordinance. No other city in New York State has a residency law. Elsewhere in the Nation, residency requirements have been adopted by a number of cities, including Houston, San Francisco, Chicago, and by Washington, D.C. ☐

Book Reviews



Nice protection if you can get it

Facing Mechanization: The West Coast Longshore Plan. By Lincoln Fairley. Los Angeles, University of California, Institute of Industrial Relations, 1979. 447 pp. (Monograph Series, 23.) $8.50, paper.

Twenty years have passed since the much-heralded mechanization and modernization agreement was negotiated by the Pacific Maritime Association and the independent International Longshoremen's and Warehousemen's Union covering Pacific Coast longshore operations. This was a major cynosure coming as it did in a climate in which work rules were active issues also in east coast longshoring, in railroads, meatpacking, and in steel among other leading bargaining situations. The personalities and backgrounds of the leading protagonists and the history of west coast longshore labor relations added to the attention given to the maritime agreement. There was Harry Bridges, long-time president of the ILWU, with his left-wing background, and his leadership of the union through the initial period of virtual internecine warfare with stevedores over work rules, which culminated in what was touted as the "new look" in the labor-management relationship. It remained for Paul St. Sure, negotiating for almost a decade on behalf of the Pacific Maritime Association, with Bridges, to turn the new look from a standoff relationship, to one which is regarded as innovative and pattern setting.

It is the long, tortuous, and delicate foundation laying for the M and M agreement, together with the metamorphoses of the agreement, that Lincoln Fairley treats in this study. That it is an admirable narrative analysis is due to Fairley's long service, from 1946 to 1967, as research director of the International Longshoremen's and Warehousemen's Union; his analytical abilities and background; and his subsequent service as an area arbitrator under the agreement by appointment of both the association and the union. Fairley had ample association with and understanding of the factors involved in the preparations for and modification of the M and M plan. Fairley does not claim to have been involved in deliberations which took place at the leadership levels, notably involving Bridges and St. Sure directly; rather it is clear that his evaluation is that of an observer.

Fairley takes us through the background and structure of the west coast relationship. Underlying the ability to achieve agreement was the coastwide organization of employers and the International Longshoremen's and Warehousemen's Union as well as the joint control of the longshore labor force through the dispatch halls in each of the ports. The hiring halls assured a balance between labor supply and demand, with relative equality in longshoremen's earnings and equitable labor distribution among ship operators and stevedores, as basic operational features. In the fifties, the prewar legalistic approach to contract enforcement was carefully avoided, and expressed employer dissatisfaction with restrictive work rules in the ports was approached through continuing discussions.

In the union, the periodic coastwide caucuses of delegates representing the union locals played an integral role in the educative process, with full and frank study of the impact of mechanization and of the likely deleterious effect of adhering to the former union policy of refusing to alter work rules. Mutual agreement in 1959 that none of the registered workforce would be laid off made possible the agreement in 1960 for basically a "buy-out" of the restrictive provisions, with reductions in gang size and increased flexibility in worker use. Funds were set up to encourage early retirement and to guarantee 35 hours work or pay per week. The former was effective; the latter was not required and was dropped in 1966. The success of the first contract resulted in renewal with substantial wage increases.

As Fairley points out, it was during the renewal period of the M and M agreement, from 1966 to 1971, that a combination of unanticipated factors led to dissatisfaction. Despite the substantial increase in earnings under the 1966 agreement, these were eroded by the unanticipated rise in living costs from 1968 on. The annual hours worked by the "A" men fell off, with the decline in shipments to Southeast Asia, and the unexpected explosive effect of the container revolution. The work or pay guarantee was restored. An effort to retain some of the lost work opportunities by agreement to have containers loaded at waterfront container freight stations, under jurisdiction of the International Longshoremen's and Warehousemen's Union, proved to be abortive in the face of Teamster jurisdiction and decisions by the National Labor Relations Board.

There is a continuous questing approach throughout Fairley's intensive analysis of this adaptation of the modernization of maritime transport. All of the criticisms leveled against the union acceptance of the change are set out. He cites the great gains made in productivity and labor-cost savings which accrued to shippers, ship operators, and stevedores. The continuing undercurrent of skepticism and actual opposition of secondary union officials and substantial minorities of rank-and-file union members, as expressed in the voting on the agreements, are detailed. Cited are the views of Marxists that the agreement was class collaborationist, betraying the union's apparent left-wing orientation. Cited at several points is the view that the west coast union should have held out for protection of the role of the gang, as had the east coast International Longshoremen's Association. Acceptance of technology, in the view of some critics, has made for alienation in work relationships, through growing routinization of the longshoremen's work, displacement of gangs, and growing "steady" work.

While stress is placed on the contrasting east coast resistance to the manning and work rule concessions, there is insufficient treatment of the contrasting institutional and structural labor-management relations on the two coasts. Rather submerged is explanation of the decentralized bargaining structure on the east coast, the difference in waterfront jurisdiction on the two coasts, and hardly treated at all are the divergent approaches to job security. As this reviewer has pointed out, the International Longshoremen's and Warehousemen's Union apparently did not emphasize the role of the gang because sufficient job security was achieved through the dispatch hall, with equalization of earnings and assurance of employment for registered longshoremen. On the east coast, in the absence of dispatch halls, the regular gangs provided the persistent and basic avenues for job security and earnings. Fairley concludes that institutional differences probably accounted for the apparently divergent policies. ("Longshoremen and the Modernization of Cargo Handling in the United States," *International Labor Review*, March 1973, pp. 272–74.)

Fairley finds the 20-year developments advantageous to the union and its members, although he apparently is unwilling to concede completely that there could not have been a more deliberate and gradual yielding of the work rules. While the registered longshore workforce and man-hours worked have declined by 40 percent since 1960, the longshore hourly rate has increased fourfold with earnings averaging $26,000 to $30,000 per year for registered longshoremen. He points out that even the older men tend to welcome the elimination of the former back-breaking work, and enjoy operating the new machines. Even with the work or pay guarantee, they continue to have the contractual right to work only when they please, and to go hunting and fishing when they want to. The young men in the southern ports, who have not experienced the early issues and battles of the union, are more concerned about wages. Thus, in contrast to the rank-and-file opposition in the thirties to "steady" work for single employees, the younger men are prepared to accept such work now required for the operation of complex and costly machinery. Fairley concludes that: ". . . though membership has declined, no one has been laid off, earnings have risen, and with a wage guarantee and a good pension plan west coast longshoremen continue to enjoy a unique degree of lifetime security."

In summary, the labor-management adjustments to maritime industry modernization mean that, so long as the volume of cargo handled grows in the United States, the longshoring occupation will continue to be in the forefront of regular and well-paid occupations in sharp contrast to the casual employment offered in this industry hardly 50 years ago.

Working women on the rise? Yes and no

The Subtle Revolution: Women At Work. Edited by Ralph E. Smith. Washington, The Urban Institute, 1979. 255 pp. $7.50, paper.

The rapid growth of the female labor force—and the expectation that this growth will continue to mushroom as we look towards the 1990's—has created the need for a comprehensive analysis of women at work. *The Subtle Revolution*, edited by Ralph E. Smith, appears to be the most ambitious effort so far to provide historical analyses and long-range projections. And because it is the intent of the volume's six authors to make a significant impact on public policy, the ambitiousness of the work is both its strength and its weakness.

Over the past 30 years, 6 out of 10 additions to the workplace have been female and it is estimated one million women will be entering the work force each year in the 1980's. But despite some gains in certain areas, the ratio of women's earnings to men's has actually dropped from about 63 percent in the mid-1950's to below 60 percent in the mid-1960's and 1970's. This alone demonstrates the importance of a volume that analyzes the effects of women's employment on the family structure, the workplace, and the tax and social security systems, and examines the many myths that keep women's pay so far below men's.

For example, studies included in this book indicate clearly that most women work because they have to, although inflation—unfortunately relegated to a lesser role because of the long-range nature of the study—often blurs the line between choice and need. Women's workplace commitment, the authors show, is comparable to men's, although because many women's jobs are dead end and low-paying, women's commitment toward individual jobs may be less. And myths and early studies that indicate damage to marriages or to the children of working women are carefully examined and contradicted.

Also examined closely are what the authors consider the inequities facing the growing army of female second earners from the Federal income tax system and the social security system. Their recommendations are somewhat controversial—measures to ease the marriage tax penalty and earnings-sharing in social security—but they can provide a framework for significant policy debate.

In one major area, however, the authors' analysis and conclusions are likely instead to distort discussion on a fundamental question—the pay gap between men and women and how to narrow it. In her study, Nancy Barrett correctly identifies occupational segregation as the main obstacle to narrowing the pay gap. But her basic conclusion is that the chief way to narrow it is for women to "increase their representation in jobs formerly dominated by men" and to move into "more responsible jobs with good pay."

This ignores high unemployment in many fields considered "nontraditional" for women and further consigns the jobs held by the majority of women—clerical, service, health—to unimportance. One of the most significant current efforts in relation to women in the workplace is research into comparable worth—analysis of jobs in terms of various factors rather than traditional market value—to determine their worth. Pioneering in these efforts are labor unions that represent women officeworkers, particularly in the public sector. This book contains not one word about upgrading the pay of "women's-type" jobs, and there are only two paragraphs that discuss unions.

Women workers currently constitute 23.5 percent of all union membership, and approximately 17 percent of the female work force is covered by a collective bargaining agreement. This can be a major avenue for upgrading women's pay and other conditions of employment; women in unions make significantly more than nonunion women. Unions such as the American Federation of State, County and Municipal Employees have pioneered comparable worth studies across the Nation. The Amalgamated Clothing Workers of America has instituted child-care centers for employees. A number of unions sponsor training programs to help break down obstacles to promotions many women workers face. By ignoring these developments, the book obscures a major avenue for improvement of the pay and jobs that are largely held and will continue to be held by women.

However, *The Subtle Revolution* does provide a useful and comprehensive compilation of data and analysis. But because its historical perspective and long-range approach do not take into account a number of current economic trends and situations, some of its conclusions and recommendations should be examined carefully in terms of immediate public policy.

Economic portrait of China

China's Economy: A Basic Guide. By Christopher Howe. New York, Basic Books, Inc., 1978. 248 pp., appendix. $16 cloth; $4.95, paper.

Recognition of the People's Republic of China last year did for Americans of this generation what Marco Polo did centuries earlier for Europeans—it opened trade, economic exchange, and tourism between the United States and China. It also made Americans increasingly interested in the basic economic facts of one of the largest land masses in the world under a single government and a country with the largest population.

Economic data on the People's Republic of China has been almost nonexistent from 1960 to 1971, and sketchy after 1971. Christopher Howe fills part of this gap by presenting a chronology of events in China, as well as tables and text on the current status of Chinese resources. Among the valuable appendixes are biographical notes on persons frequently referred to in literature on the Chinese economy, Chinese measures and Western equivalents, and how to find out about and keep up with economic developments in China.

The author makes the point that Chinese leaders have had a continuous struggle with problems of food and population. At the international level, China now shares with other developing countries a growing preoccupation with raw material prices, the working of international economic institutions, and the general problems of world economic order.

Howe writes that in 1949 the Chinese economy reflected two fundamental developments: a crisis in the long-term relationship between the growth of population and the growth of the food supply and the beginning of industrialization that started during the First World War. Much of the economic dislocation and lack of investment in China was due to war. From 1927, the Chinese were fighting a civil war and from 1937, they were fighting the Japanese, according to Howe.

China's development since 1949 has been uneven. The first phase lasted from 1949 to 1952. The Communist Party took control of the monetary, fiscal, and trade systems and implemented a land reform. The latter was a traumatic event which eliminated the political and economic power of the landlords and distributed land and other assets to the rural population.

Howe labels the four phases of development since 1952 as (1) the periods of fastest growth (1952–59); (2) the Great Depression (1959–61); (3) readjustment and the Cultural Revolution (1961–70); and (4) the revival of growth with trade (1970–77).

The First Five-Year Plan (1953–57) raised by about 20 percent the share of the nation's resources to be invested and proposed that these resources be used for the development of heavy industry.

The Plan's impact on agricultural collectivism was dramatic. By March 1956, more than 90 percent of all the Chinese peasants were in cooperatives and by 1957, virtually all were in the 680,000 more sophisticated cooperatives. Thus, a revolution planned to take 15 years was over in little more than 1 year, says Howe.

But the results were not satisfactory. Growth of agriculture was still too slow. Growth of urban employment was slow. Relations with the Soviet Union (upon which industrial assistance depended) were worsening. This crisis led Chairman Mao (who dominated China's political life from the 1930's to his death) to launch the most extraordinary economic adventure the world has ever seen—the Great Leap Forward of 1958. It embodied changes in ownership and organization combined with a radical psychological transformation that would stimulate people to work more intensively, more creatively, more selflessly.

As the Leap went on into 1959, administrative confusion deepened and the consequences of strain, of the misuse of resources, and of sheer human exhaustion became increasingly serious. When the end came, it coincided with the withdrawal of Soviet assistance and a succession of natural disasters.

From 1962 to 1965, China's economic position improved. However, Howe points out that the political situation remained difficult. Mao believed the retreat from the Leap had led to corruption—to selfish, anti-Socialist economic behavior, and to the entrenchment of his enemies in the bureaucracy. By mid-1966, the revival of the economy finally made it possible for Mao to launch a campaign against his enemies. Thus, unlike his Leap, Mao's Cultural Revolution was not launched to remedy economic problems. It was mainly a political struggle.

In the 1970's, claims Howe, the Chinese economy reawoke after years of isolation. Chou En-lai, prime minister and a power in economic matters, died in April 1976. Mao died in September 1976, and his death was followed immediately by signs of a decisive new phase of economic policy. The critics of Chou's program were identified as the "Gang of Four" and included Mao's widow. Howe says that the disgrace of the Gang has been very important because it has been possible to blame them for many of China's economic troubles.

Howe indicates that the 1953 census was the first count in China to approach modern standards of enumeration. It was undertaken because information about the population was needed for preparation of the First Five Year Plan. The Chinese population is a young one, Howe points out. The bulk of it is of working age (15 to 64). The number of trained or educated workers grew very rapidly between the 1950's and the early 1960's.

The basic sectors of the Chinese economic system are producers, consumers, and the government. The "producers" are mainly industrial enterprises, people's communes, and other collectively organized units. The State owns nearly all industrial organizations with significant capital equipment. A collective sector (collective units are owned by their workers) employs over a third of all industrial workers and produces 14 percent of total output. In agriculture, approximately 90 percent of cultivated land and irrigation equipment is collectively owned, mainly by "teams" which often correspond to villages.

China's Economy draws on standard Chinese, Japanese, U.S., and English sources and on documents as well as on firsthand observations and interviews. It is the best up-to-date survey of the Chinese economy now in print with an analysis of agriculture, industry, foreign trade, population, and incomes for the nonspecialist reader.

Current Labor Statistics

Notes on Current Labor Statistics 70

Schedule of release dates for major BLS statistical series 70

Employment data from household survey. Definitions and notes 71
1. Employment status of noninstitutional population, selected years, 1950–79 71
2. Employment status by sex, age, and race, seasonally adjusted 72
3. Selected employment indicators, seasonally adjusted 73
4. Selected unemployment indicators, seasonally adjusted 74
5. Unemployment rates, by sex and age, seasonally adjusted 75
6. Unemployed persons, by reason for unemployment, seasonally adjusted 75
7. Duration of unemployment, seasonally adjusted 75

Employment, hours, and earnings data from establishment surveys. Definitions and notes 76
8. Employment by industry, 1950–79 77
9. Employment by State 77
10. Employment by industry division and major manufacturing group 78
11. Employment by industry division and major manufacturing group, seasonally adjusted 79
12. Labor turnover rates in manufacturing, 1977 to date 80
13. Labor turnover rates in manufacturing, by major industry group 80
14. Hours and earnings, by industry division, 1949–79 81
15. Weekly hours, by industry division and major manufacturing group 82
16. Weekly hours, by industry division and major manufacturing group, seasonally adjusted 83
17. Hourly earnings, by industry division and major manufacturing group 84
18. Hourly Earnings Index, by industry division, seasonally adjusted 84
19. Weekly earnings, by industry division and major manufacturing group 85
20. Gross and spendable weekly earnings, in current and 1967 dollars, 1960 to date 86

Unemployment insurance data. Definitions and notes 87
21. Unemployment insurance and employment service operations 87

Price data. Definitions and notes 88
22. Consumer Price Index, 1967–79 89
23. Consumer Price Index, U.S. city average, general summary and selected items 89
24. Consumer Price Index, cross classification of region and population size class 95
25. Consumer Price Index, selected areas 96
26. Producer Price Indexes, by stage of processing 97
27. Producer Price Indexes, by commodity groupings 98
28. Producer Price Indexes, for special commodity groupings 100
29. Producer Price Indexes, by durability of product 100
30. Producer Price Indexes for the output of selected SIC industries 100

Productivity data. Definitions and notes 103
31. Indexes of productivity and related data, selected years, 1950–79 103
32. Annual percent change in productivity and related data, 1969–79 104
33. Indexes of productivity, hourly compensation, and unit costs 104
34. Percent change in productivity, hourly compensation, and unit costs 105

Labor-management data. Definitions and notes 106
35. Wage and benefit settlements in major collective bargaining units, 1975 to date 106
36. Effective wage rate adjustments going into effect in major collective bargaining units, 1975 to date 107
37. Work stoppages, 1947 to date 107

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics. A brief introduction to each group of tables provides definitions, notes on the data, sources, and other material usually found in footnotes.

Readers who need additional information are invited to consult the BLS regional offices listed on the inside front cover of this issue of the *Review*. Some general notes applicable to several series are given below.

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might otherwise mask short-term movements of the statistical series. Tables containing these data are identified as "seasonally adjusted." Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years. For a technical discussion of the method used to make seasonal adjustments, see "Appendix A. The BLS Seasonal Factor Method," *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), pp. 272–78, and *X-11 Variant of the Census Method II Seasonal Adjustment Program*, Technical Paper No. 15 (Bureau of the Census, 1967). Seasonally adjusted labor force data in tables 2–7 were last revised in the February 1980 issue of the *Review* to reflect the preceding year's experience. Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X-11/ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method. A detailed description of the procedure appears in *The X-11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada Catalogue No. 12-564E, September 1979).

The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. Revisions of historical data continue to be made only at the end of each calendar year. Annual revision of the seasonally adjusted payroll data in tables 11, 13, 16, and 18 was last introduced in the November 1979 issue of the *Review*. New seasonal factors for productivity data in tables 33 and 34 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The resulting values are described as "real," "constant," or "1967" dollars.

Availability of information. Data that supplement the tables in this section are published by the Bureau of Labor Statistics in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule given below. The *Handbook of Labor Statistics 1978*, Bulletin 2000, provides more detailed data and greater historical coverage for most of the statistical series presented in the *Monthly Labor Review*. More information from the household and establishment surveys is provided in *Employment and Earnings*, a monthly publication of the Bureau, and in two comprehensive data books issued annually—*Employment and Earnings, United States* and *Employment and Earnings, States and Areas*. More detailed information on wages and other aspects of collective bargaining appears in the monthly periodical, *Current Wage Developments*. More detailed price information is published each month in the periodicals, the *CPI Detailed Report* and *Producer Prices and Price Indexes*.

Symbols

p = preliminary. To improve the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.

Schedule of release dates for major BLS statistical series

Title and frequency (monthly except where indicated)	Release date	Period covered	Release date	Period covered	MLR table number
Employment situation	July 3	June	August 1	July	1–11
Producer Price Index	July 8	June	August 15	July	26–30
Consumer Price Index	July 23	June	August 22	July	22–25
Real earnings	July 23	June	August 22	July	14–20
Major collective bargaining settlements (quarterly)	July 25	1st half	....	....	35–36
Productivity and costs (quarterly):					
Nonfarm business and manufacturing	July 28	2nd quarter	....	....	31–34
Nonfinancial corporations	....	....	August 27	2nd quarter	31–34
Work stoppages	July 29	June	August 28	July	37
Labor turnover in manufacturing	July 30	June	August 29	July	12–13

EMPLOYMENT DATA FROM THE HOUSEHOLD SURVEY

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 65,000 households beginning in January 1980, selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons are (1) those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population; the **total labor force** includes military personnel. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons retired, those engaged in their own housework, those not working while attending school, those unable to work because of longterm illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy.

Full-time workers are those employed at least 35 hours a week; **part-time workers** are those who work fewer hours. Workers on part-time schedules for economic reasons (such as slack work, terminating or starting a job during the week, material shortages, or inability to find full-time work) are among those counted as being on full-time status, under the assumption that they would be working full time if conditions permitted. The survey classifies unemployed persons in full-time or part-time status by their reported preferences for full-time or part-time work.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data presented in table 1. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 2–7 are seasonally adjusted, based on the seasonal experience through December 1979.

1. Employment status of the noninstitutional population, 16 years and over, selected years, 1950–79

[Numbers in thousands]

Year	Total noninstitutional population	Total labor force		Civilian labor force						Not in labor force
		Number	Percent of population	Total	Employed			Unemployed

EMPLOYMENT, HOURS, AND EARNINGS DATA FROM ESTABLISHMENT SURVEYS

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by 162,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

LABOR TURNOVER DATA in this section are compiled from personnel records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies. A sample of 40,000 establishments represents all industries in the manufacturing and mining sectors of the economy.

Definitions

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 14–20 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in transportation and public utilities, in wholesale and retail trade, in finance, insurance, and real estate, and in service industries. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to eliminate the effects of price change. The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries. **Spendable earnings** are earnings from which estimated social security and Federal income taxes have been deducted. The Bureau of Labor Statistics computes spendable earnings from gross weekly earnings for only two illustrative cases: (1) a worker with no dependents and (2) a married worker with three dependents.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

Labor turnover is the movement of all wage and salary workers from one employment status to another. **Accession rates** indicate the average number of persons added to a payroll in a given period per 100 employees; **separation rates** indicate the average number dropped from a payroll per 100 employees. Although month-to-month changes in employment can be calculated from the labor turnover data, the results are not comparable with employment data from the employment and payroll survey. The labor turnover survey measures changes during the calendar month while the employment and payroll survey measures changes from midmonth to midmonth.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of September 1979 data, published in the November 1979 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Complete comparable historical unadjusted and seasonally adjusted data are published in a Supplement to Employment and Earnings (unadjusted data from April 1977 through June 1979 and seasonally adjusted data from January 1974 through June 1979) and in *Employment and Earnings, United States, 1909–78*, BLS Bulletin 1312–11 (for prior periods).

Data on recalls were shown for the first time in tables 12 and 13 in the January 1978 issue of the *Review*. For a detailed discussion of the recalls series, along with historical data, see "New Series on Recalls from the Labor Turnover Survey," *Employment and Earnings*, December 1977, pp. 10–19.

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20. See also *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976).

The formulas used to construct the spendable average weekly earnings series reflect the latest provisions of the Federal income tax and social security tax laws. For the spendable average weekly earnings formulas for the years 1978–80, see *Employment and Earnings*, March 1980, pp. 10–11. Real earnings data are adjusted using the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

NOTE: The earnings expressed in 1967 dollars have been adjusted for changes in price level as measured by the Bureau's Consumer Price Index for Urban Wage Earners and Clerical Workers.

These series are described in "The Spendable Earnings Series: A Technical Note on its Calculation," **Employment and Earnings and Monthly Report on the Labor Force,** February 1969, pp. 6–13. See also "Spendable Earnings Formulas, 1978–80," **Employment and Earnings,** March 1980, pp. 10–11.

UNEMPLOYMENT INSURANCE DATA

UNEMPLOYMENT INSURANCE DATA are compiled monthly by the Employment and Training Administration of the U.S. Department of Labor from records of State and Federal unemployment insurance claims filed and benefits paid. Railroad unemployment insurance data are prepared by the U.S. Railroad Retirement Board.

Definitions

Data for **all programs** represent an unduplicated count of insured unemployment under State programs, Unemployment Compensation for Ex-Servicemen, and Unemployment Compensation for Federal Employees, and the Railroad Insurance Act.

Under both State and Federal unemployment insurance programs for civilian employees, insured workers must report the completion of at least 1 week of unemployment before they are defined as unemployed. Persons not covered by unemployment insurance (about one-third of the labor force) and those who have exhausted or not yet earned benefit rights are excluded from the scope of the survey. **Initial claims** are notices filed by persons in unemployment insurance programs to indicate they are out of work and wish to begin receiving compensation. A claimant who continued to be unemployed a full week is then counted in the insured unemployment figure. The **rate of insured unemployment** expresses the number of insured unemployed as a percent of the average insured employment in a 12-month period.

An **application** for benefits is filed by a railroad worker at the beginning of his first period of unemployment in a benefit year; no application is required for subsequent periods in the same year. **Number of payments** are payments made in 14-day registration periods. The **average amount of benefit payment** is an average for all compensable periods, not adjusted for recovery of overpayments or settlement of underpayments. However, **total benefits paid** have been adjusted.

21. Unemployment insurance and employment service operations

[All items except average benefits amounts are in thousands]

[1] Initial claims and State insured unemployment include data under the program for Puerto Rican sugarcane workers.

[2] Includes interstate claims for the Virgin Islands. Excludes transition claims under State programs.

[3] Excludes data on claims and payments made jointly with other programs.

[4] Includes the Virgin Islands. Excludes data on claims and payments made jointly with State programs.

[5] Cumulative total for fiscal year (October 1 - September 30).

NOTE: Data for Puerto Rico included. Dashes indicate data not available.

PRICE DATA

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Definitions

The Consumer Price Index is a monthly statistical measure of the average change in prices in a fixed market basket of goods and services. Effective with the January 1978 index, the Bureau of Labor Statistics began publishing CPI's for two groups of the population. One index, a new CPI for All Urban Consumers, covers 80 percent of the total noninstitutional population; and the other index, a revised CPI for Urban Wage Earners and Clerical Workers, covers about half the new index population. The All Urban Consumers index includes, in addition to wage earners and clerical workers, professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctor's and dentist's fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items is kept essentially unchanged between major revisions so that only price changes will be measured. Prices are collected from over 18,000 tenants, 24,000 retail establishments, and 18,000 housing units for property taxes in 85 urban areas across the country. All taxes directly associated with the purchase and use of items are included in the index. Because the CPI's are based on the expenditures of two population groups in 1972–73, they may not accurately reflect the experience of individual families and single persons with different buying habits.

Though the CPI is often called the "Cost-of-Living Index," it measures only price change, which is just one of several important factors affecting living costs. Area indexes do not measure differences in the level of prices among cities. They only measure the average change in prices for each area since the base period.

Producer Price Indexes measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes contains about 2,800 commodities and about 10,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The universe includes all commodities produced or imported for sale in commercial transactions in primary markets in the United States.

Producer Price Indexes can be organized by stage of processing or by commodity. The stage of processing structure organizes products by degree of fabrication (that is, finished goods, intermediate or semifinished goods, and crude materials). The commodity structure organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States, from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

In calculating Producer Price Indexes, price changes for the various commodities are averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage of processing groupings, commodity groupings, durability of product groupings, and a number of special composite groupings.

Price indexes for the output of selected SIC industries measure average price changes in commodities produced by particular industries, as defined in the *Standard Industrial Classification Manual 1972* (Washington, U.S. Office of Management and Budget, 1972). These indexes are derived from several price series, combined to match the economic activity of the specified industry and weighted by the value of shipments in the industry. They use data from comprehensive industrial censuses conducted by the U.S. Bureau of the Census and the U.S. Department of Agriculture.

Notes on the data

Beginning with the May 1978 issue of the *Review*, regional CPI's cross classified by population size, were introduced. These indexes will enable users in local areas for which an index is not published to get a better approximation of the CPI for their area by using the appropriate population size class measure for their region. The cross-classified indexes will be published bimonthly. (See table 24.)

For further details about the new and the revised indexes and a comparison of various aspects of these indexes with the old unrevised CPI, see *Facts About the Revised Consumer Price Index*, a pamphlet in the Consumer Price Index Revision 1978 series. See also *The Consumer Price Index: Concepts and Content Over the Years*. Report 517, revised edition (Bureau of Labor Statistics, May 1978).

For interarea comparisons of living costs at three hypothetical standards of living, see the family budget data published in the *Handbook of Labor Statistics, 1977*, Bulletin 1966 (Bureau of Labor Statistics, 1977), tables 122–133. Additional data and analysis on price changes are provided in the *CPI Detailed Report* and *Producer Prices and Price Indexes*, both monthly publications of the Bureau.

As of January 1976, the Wholesale Price Index (as it was then called) incorporated a revised weighting structure reflecting 1972 values of shipments. From January 1967 through December 1975, 1963 values of shipments were used as weights.

For a discussion of the general method of computing consumer, producer, and industry price indexes, see *BLS Handbook of Methods for Surveys and Studies*, Bulletin 1910 (Bureau of Labor Statistics, 1976), chapters 13–15. See also John F. Early, "Improving the measurement of producer price change," *Monthly Labor Review*, April 1978, pp. 7–15. For industry prices, see also Bennett R. Moss, "Industry and Sector Price Indexes," *Monthly Labor Review*, August 1965, pp. 974–82.

[1] Data for January 1980 have been revised to reflect the availability of late reports and corrections by respondents. All data are subject to revision 4 months after original publication.

[2] Prices for natural gas are lagged 1 month.

[3] Includes only domestic production.

[4] Most prices for refined petroleum products are lagged 1 month.

[5] Some prices for industrial chemicals are lagged 1 month.

28. Producer Price Indexes, for special commodity groupings

[1967 = 100 unless otherwise specified]

Commodity grouping	Annual average 1978	1979								1980				
		May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.[1]	Feb.	Mar.	Apr.	May
All commodities — less farm products	208.4	230.1	232.0	235.4	237.5	241.4	245.3	247.0	249.5	255.7	260.5	262.6	264.3	265.4

PRODUCTIVITY DATA

PRODUCTIVITY DATA are compiled by the Bureau of Labor Statistics from establishment data and from estimates of compensation and output supplied by the U.S. Department of Commerce and the Federal Reserve Board.

Definitions

Output is the constant dollar gross domestic product produced in a given period. Indexes of **output per hour of labor input,** or labor productivity, measure the value of goods and services produced per hour of labor. **Compensation per hour** includes wages and salaries of employees plus employers' contributions for social insurance and private benefit plans. The data also include an estimate of wages, salaries, and supplementary payments for the self-employed, except for nonfinancial corporations, in which there are no self-employed. **Real compensation per hour** is compensation per hour adjusted by the Consumer Price Index for All Urban Consumers.

Unit labor cost measures the labor compensation cost required to produce one unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from the current dollar gross domestic product and dividing by output. In these tables, **Unit nonlabor costs** contain all the components of unit nonlabor payments except unit profits. **Unit profits** include corporate profits and inventory valuation adjustments per unit of output.

The **implicit price deflator** is derived by dividing the current dollar estimate of gross product by the constant dollar estimate, making the deflator, in effect, a price index for gross product of the sector reported.

The use of the term "man-hours" to identify the labor component of productivity and costs, in tables 31 through 34, has been discontinued. **Hours of all persons** is now used to describe the labor input of payroll workers, self-employed persons, and unpaid family workers. **Output per all-employee hour** is now used to describe labor productivity in nonfinancial corporations where there are no self-employed.

Notes on the data

In the private business sector and the nonfarm business sector, the basis for the output measure employed in the computation of output per hour is Gross Domestic Product rather than Gross National Product. Computation of hours includes estimates of nonfarm and farm proprietor hours.

Output data are supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are from the Bureau of Economic Analysis and the Bureau of Labor Statistics.

Beginning with the September 1976 issue of the *Review,* tables 31–34 were revised to reflect changeover to the new series—private business sector and nonfarm business sector—which differ from the previously published total private economy and nonfarm sector in that output imputed for owner-occupied dwellings and the household and institutions sectors, as well as the statistical discrepancy, are omitted. For a detailed explanation, see J. R. Norsworthy and L. J. Fulco, "New sector definitions for productivity series," *Monthly Labor Review,* October 1976, pages 40–42.

LABOR-MANAGEMENT DATA

MAJOR COLLECTIVE BARGAINING DATA are obtained from contracts on file at the Bureau of Labor Statistics, direct contact with the parties, and from secondary sources. Additional detail is published in *Current Wage Developments*, a monthly periodical of the Bureau. Data on work stoppages are based on confidential responses to questionnaires mailed by the Bureau of Labor Statistics to parties involved in work stoppages. Stoppages initially come to the attention of the Bureau from reports of Federal and State mediation agencies, newspapers, and union and industry publications.

Definitions

Data on wage changes apply to private nonfarm industry agreements covering 1,000 workers or more. Data on wage and benefit changes *combined* apply only to those agreements covering 5,000 workers or more. **First-year wage settlements** refer to pay changes going into effect within the first 12 months after the effective date of the agreement. **Changes over the life of the agreement** refer to total agreed upon settlements (exclusive of potential cost-of-living escalator adjustments) expressed at an average annual rate. **Wage-rate changes** are expressed as a percent of straight-time hourly earnings, while **wage and benefit changes** are expressed as a percent of total compensation.

Effective wage-rate adjustments going into effect in major bargaining units measure changes actually placed into effect during the reference period, whether the result of a newly negotiated increase, a deferred increase negotiated in an earlier year, or as a result of a cost-of-living escalator adjustment. Average adjustments are affected by workers receiving no adjustment, as well as by those receiving increases or decreases.

Work stoppages include all known strikes or lockouts involving six workers or more and lasting a full shift or longer. Data cover all workers idle one shift or more in establishments directly involved in a stoppage. They do not measure the indirect or secondary effect on other establishments whose employees are idle owing to material or service shortages.

35. Wage and benefit settlements in major collective bargaining units, 1975 to date

[In percent]

Sector and measure	Annual average					Quarterly average						
	1975	1976	1977	1978	1979	1978		1979				1980 p

How to order BLS publications

PERIODICALS

Order from (and make checks payable to) Superintendent of Documents, Washington, D.C. 20402. For foreign subscriptions, add 25 percent.

Monthly Labor Review. The oldest and most authoritative government research journal in economics and the social sciences. Current statistics, analysis, developments in industrial relations, court decisions, book reviews. $18 a year, single copy, $2.50.

Employment and Earnings. A comprehensive monthly report on employment, hours, earnings, and labor turnover by industry, area, occupation, et cetera $22 a year, single copy $2.75.

Occupational Outlook Quarterly. A popular periodical designed to help high school students and guidance counselors assess career opportunities. $6 for four issues, single copy $1.75.

Current Wage Developments. A monthly report about collective bargaining settlements and unilateral management decisions about wages and benefits; statistical summaries. $12 a year, single copy $1.35.

Producer Prices and Price Indexes. A comprehensive monthly report on price movements of both farm and industrial commodities, by industry and stage of processing. $17 a year, single copy $2.25.

CPI Detailed Report. A monthly periodical featuring detailed data and charts on the Consumer Price Index. $15 a year, single copy $2.25.

PRESS RELEASES

The Bureau's statistical series are made available to news media through press releases issued in Washington. Many of the releases also are available to the public upon request. Write: Bureau of Labor Statistics, Washington, D.C. 20212.

Regional. Each of the Bureau's eight regional offices publishes reports and press releases dealing with regional data. Single copies available free from the issuing regional office.

BULLETINS AND HANDBOOKS

About 140 bulletins and handbooks published each year are for sale by regional offices of the Bureau of Labor Statistics (see inside front cover) and by the Superintendent of Documents, Washington, D.C. 20402. Make checks payable to the Superintendent of Documents. Among the bulletins and handbooks currently in print are these:

Occupational Outlook Handbook, 1978–79 Edition. Bulletin 1955. A useful resource supplying valuable assistance to all persons seeking satisfying and productive employment. $8, paperback; $11 hard cover.

BLS Handbook of Labor Statistics 1978. Bulletin 2000. A 604-page volume of historical data on the major BLS statistical series. $9.50.

Handbook of Methods. Bulletin 1910. Brief technical account of each major statistical program of the Bureau of Labor Statistics. $3.50.

BLS Measures of Compensation. Bulletin 1941. An introduction to the various measures of employee compensation; describes each series, the manner in which it is developed, its uses and limitations. $2.75.

Occupational Projections and Training Data. Bulletin 2020. Presents both general and detailed information on the relationship between occupational requirements and training needs. (Updates Bulletin 1918 published in 1976.) $3.25.

Technological Change and its Labor Impact in Five Energy Industries. Bulletin 2005. A 64-page study appraising major technological change and discussing the impact of these changes on productivity and occupations over the next 5 to 10 years. $2.40.

BLS Publications, 1972–77. Bulletin 1990. A numerical listing and subject index of bulletins and reports issued by the Bureau from 1972 through 1977, supplementing Bulletin 1749, covering 1886–1971. $1.80.

International Comparisons of Unemployment. Bulletin 1979. Brings together all of the Bureau's work on international unemployment comparisons. Describes the methods of adjusting foreign unemployment rates in 8 countries to U.S. concepts. $3.50.

Productivity Indexes for Selected Industries, 1979 Edition. Bulletin 2054. A 190-page report of indexes of output, employment, and employee hours in selected industries from 1954 to 1978. This edition contains measures for three industries previously not covered, as well as components of previously published measures in 10 industries. $5.50.

Profiles of Occupational Pay: A Chartbook. Bulletin 2037. A graphic illustration of some of the factors that affect workers' earnings. This three-part presentation looks at wage variations among and within occupations and portrays characteristics of high- and low-paying urban areas and manufacturing industries. $3.50.

REPORTS AND PAMPHLETS

Single copies available free from the BLS regional offices or from the Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

How the Government Measures Unemployment. Report 505. A concise report providing a background for appraising developments in the area of unemployment.

Directory of BLS Studies in Industrial Relations 1960–78. Report 550. A listing of studies prepared by the Division of Industrial Relations as part of the Bureau's regular program of data collection and analysis in the field of industrial relations.

Comparison of State Unemployment Insurance Laws
U.S. Department of Labor
Employment and Training Administration

Comparison of State Unemployment Insurance Laws, issued January 1, 1978, summarizes and compares significant provisions of unemployment insurance laws of the 50 States, District of Columbia, Puerto Rico and the Virgin Islands. The looseleaf format permits pages to be removed and replaced by pages with current data.

- Gives information on employer and employee coverage, financing methods, benefit payments, eligibility requirements, and administrative organization.
- Includes rules, regulations, opinions of attorneys general, or court decisions that implement State Statutes, with notes indicating their source.
- Provides factual information, by State, in Tables.
- Compares the laws of four States which provide benefits for unemployment due to nonoccupational disability.
- Includes brief description of unemployment insurance programs for Federal civilian employees and ex-servicemen and Federal training allowances and readjustment programs administered by State employment security agencies.

Comparison of State Unemployment Insurance Laws, issued January 1, 1978, distributed free to State agencies, is for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price for basic document and 5 revisions is $12 domestic and $15 foreign. Send correspondence on circulation and subscription matters (including address changes) to the Superintendent of Documents.

Labor Month In Review

OCCUPATIONAL DISEASES. In *An Interim Report to Congress on Occupational Diseases,* Secretary of Labor Ray Marshall discussed the difficulty of linking diseases to employment and the limitations on income support for those afflicted. Excerpts:

Diagnosis. Almost 2 million workers report they are severely or partially disabled from an occupationally related disease. Approximately 700,000 suffer long-term total disability. The 1.2 million workers partially disabled are either temporarily out of the labor force because of the impairment or limited in the work they can perform.

Because of the length of time between exposure to an industrial health hazard and the onset of disability or death, it is difficult, in many cases, to link diseases to employment. For example, symptoms of pulmonary disease or cancer can occur 4 to 10 hours after exposure to cadmium, 10 to 20 years after exposure to asbestos, and 20 to 45 years after exposure to silica.

The major health effects now linked to asbestos exposure are asbestosis (a chronic lung disease) and various types of cancer. Once established, asbestosis progresses even after exposure is terminated. The two major asbestos-related cancers are lung cancer (clinically indistinguishable from lung cancer of other causes) and mesothelioma (a rare cancer of the linings of the lungs and abdominal cavity). In addition, asbestos exposure is associated with increased risk of cancer of the esophagus, larnyx, oropharynx, stomach, colon, rectum, and recently with kidney cancer. In 1974, at least 1.6 million workers were exposed to asbestos.

Byssinosis is the most significant health hazard resulting from exposure to cotton dust. The conditions (chest tightness, wheezing, shortness of breath) generally are reversible during the early stages. The more serious (chronic) effects may be arrested (but not reversed) if the worker avoids further exposure. Diagnosis is difficult because the symptoms of chronic byssinosis are indistinguishable from those of chronic bronchitis and emphysema. An estimated 600,000 workers are currently exposed to cotton dust.

The most common form of disease resulting from silica exposure causes progressive scarring of the lungs and loss of pulmonary function. As the disease progresses, complications such as tuberculosis, other chest infections, and ultimately cardio-respiratory failure make diagnosis more difficult. There is no effective treatment to stop the progression of the disease even after removal from exposure. An estimated one million workers currently are exposed to silica.

Other hazardous substances which cause chronic respiratory disease or cancer discussed in the report are beryllium, cadmium, chromium, arsenic, nickel, coal tar products, and diisocyanates.

Income support. Public and private income support programs replace about 40 percent of the wages lost by individuals who are severely disabled from an occupational disease.

Although social security is the major source of income support for those severely disabled from an occupational disease, not all severely disabled workers are eligible for benefits. The major reason: they cannot meet the "recency of employment" requirement. Even for those eligible, there is a 5-month waiting period for cash payments and an additional waiting period of 2 years for medicare benefits.

The small percentage receiving workers' compensation benefits result, in part, from difficulties involved in establishing the work relationship of disabling illnesses.Even after establishing that an illness is occupationally related, a disabled worker still has more problems collecting benefits than those injured on the job. For example, on average, a disabled worker with an occupational disease waits a year before receiving the first compensation payment (work injury cases are settled in about 2 months); 60 percent of all occupational disease awards are initially denied (compared with 10 percent of the injury awards); and more than half of the occupational disease awards rely on compromise-and release-agreements involving small lump-sum settlements which release insurance carriers from further liability for both income maintenance and health costs (16 percent of the injury awards receive such treatment).

The *Interim Report* is available from the U.S. Department of Labor, Office of Assistant Secretary for Policy, Evaluation and Research, Washington 20210. ☐

Employment and unemployment in the first half of 1980

As the new decade began, the Nation entered a recession; employment dropped and unemployment surged; housing construction and automobile manufacturing, which strongly influence employment in other industries, showed the earliest signs of deterioration

RICHARD M. DEVENS, JR.

The relative stability of the 1979 labor market ended abruptly in early 1980. Employment growth, which started to slow down in the first quarter, dropped sharply in the second. For the first time in 2 years the unemployment rate inched up to more than 6 percent in the first quarter, and jumped to 7.5 percent in the second quarter. The quarter-to-quarter surge equaled the largest ever recorded in the series (which dates back to 1940).

The increase in unemployment was not matched by the drop in employment. (See chart 1.) This development reflects the impact of labor force entrants, as well as the complex nature of our economy which permits some sectors to continue to expand while others are laying off workers. The labor force participation rate rose slowly over the first half, reflecting continuing increases in the labor force participation of women.

Even in the relative calm of the late 1979 job market, there were signs in two important industries that foreshadowed the deterioration of the labor market. Residential housing construction and automobile manufacturing, both industries with high potential to produce "ripple effects" through the rest of the economy, have traditionally been among the first to feel the effects of deteriorating economic conditions. In late 1979 and early 1980, reports of tight financial markets, falling demand for new housing, oil price boosts, declining auto sales, high interest rates, and other indicators augured the onset of hard times in these two industries.

This article highlights recent trends in total employment and industry payrolls (particularly in the homebuilding and automobile industries), analyzes the sudden and steep rise in unemployment from the perspective of its differential impacts on groups of workers, and examines other labor market indicators to better gauge the overall magnitude of the economic downturn.

Employment declines

Total employment. The impact of production cutbacks on total employment became very obvious in the second quarter of the year. After a small rise in the first quarter, the number of persons holding jobs dropped by 900,000 in the second to 96.9 million (seasonally adjusted). (See table 1.) This was the first quarter-to-quarter employment decline in 5 years and was the third largest absolute decline recorded in the series. The only larger declines came during the 1957–58 and 1973–75 recessions. The proportion of the employed noninstitutional population fell 0.6 percentage point between the first and second quarters of 1980 to 58.4 percent, the lowest level in 2 years.

Total employment rose slightly in the first quarter of 1980. Women accounted for the entire increase, as em-

---

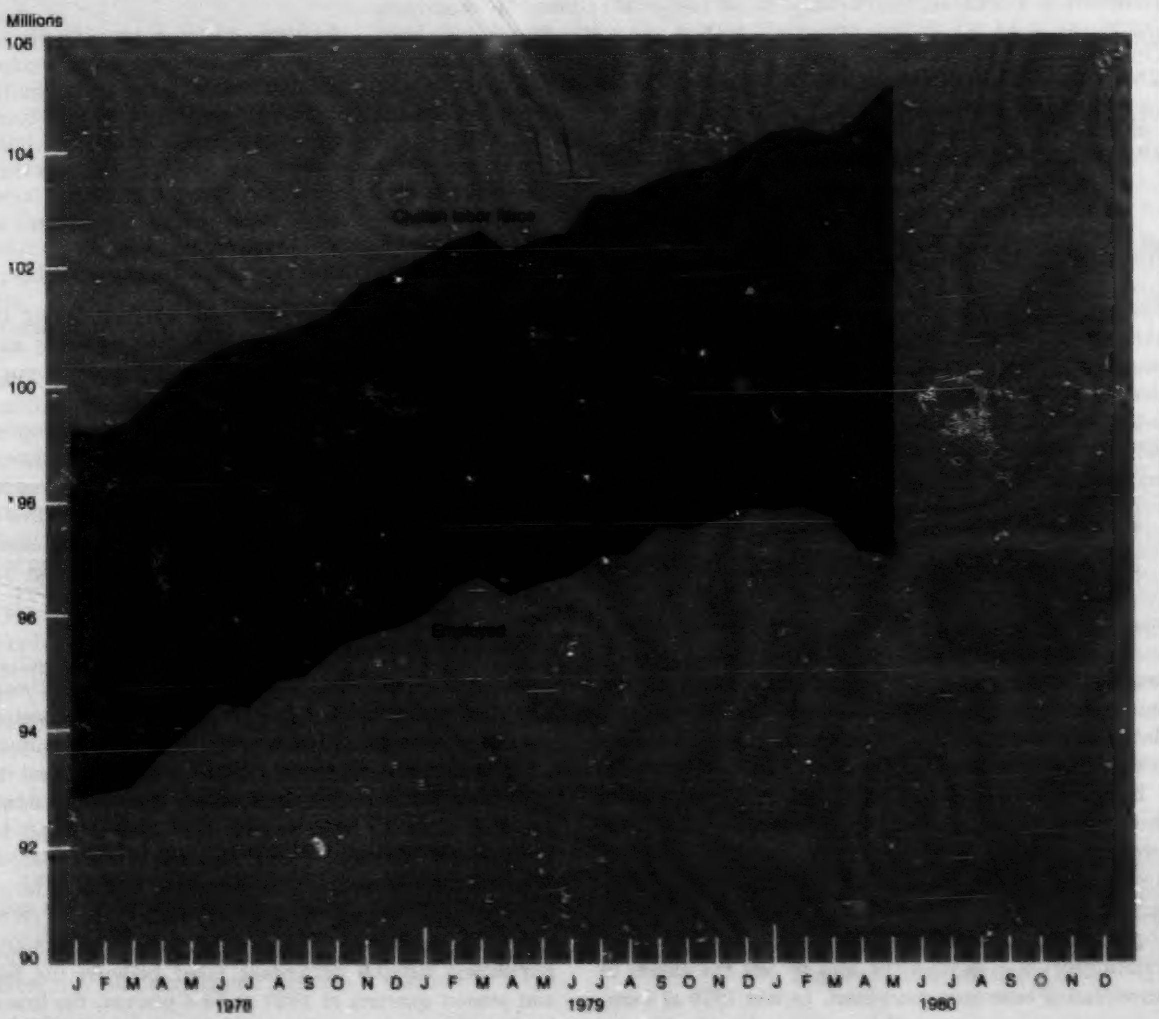
Richard M. Devens, Jr., is an economist in the Office of Current Employment Analysis, Bureau of Labor Statistics.

ployment was little changed over the quarter among men and teenagers.[1] The situation in the second quarter was reversed: teenagers suffered about a third of the decline in employment, men accounted for the remaining two-thirds, and the employment of women was unchanged.

Employment among white workers rose by 290,000 in the first 3 months, only to fall by 825,000 in the second quarter to 86.1 million, a net decline of 0.6 percent over the first half. Black workers experienced employment declines in both quarters; the declines totaled 270,000, or 2.4 percent. Employment among blacks stood at 10.8 million in the second quarter.

Industry payrolls. The second-quarter drop in payroll employment totaled 545,000 and occurred almost exclusively in the goods-producing sector of the economy. (See table 2.) Service-producing employment continued to follow its long-run upward trend, although at a considerably slower rate in the second quarter of 1980. The gains in the service sector thus partially offset the decline in the goods sector. Although some part of these divergent movements may be attributed to a long-term shift in the structure of the economy, employment has

Chart 1. Civilian labor force, the employed, and the unemployed, 1978-80



SOURCE: Current population survey.

traditionally been more cyclically sensitive in the goods-producing than in the service-producing sector.

The overall pattern of the service-producing sector masked some important differences among the several industries within this broad group. Wholesale and retail trade and transportation and public utilities were the biggest job losers in the sector (down 110,000 and 40,000, respectively) while government and services were job gainers (295,000 and 110,000). Virtually all of the Federal increase was attributable to the impact of temporary hirings for the 1980 Decennial Census.

The two industry groups that were hardest hit at the outset of the economic downturn were construction and manufacturing, both of which are in the goods-producing sector. During the second quarter of 1980, construction employment dropped 215,000 to a level of 4.4 million; manufacturing employment fell by 655,000 to 20.3 million.

Within manufacturing, job losses occurred in the second quarter of the year and were concentrated among durable goods industries. These cutbacks were pervasive: lumber and wood products, fabricated metal products, and transportation equipment all sustained substantial reductions. Except in rubber and plastics, the nondurable goods industries showed little or no change in employment in the first half of 1980.

Layoffs in manufacturing, as measured by the Bureau of Labor Statistics' labor turnover survey, which had been averaging less than 1.0 per hundred workers in early 1979, rose from 1.2 to 1.4 per hundred between the last quarter of 1979 and the first quarter of 1980. The manufacturing workweek, which, like layoffs, is considered by analysts to be a good leading indicator of the business cycle,[2] fell sharply in the spring of 1980. The aggregate hours index which reflects changes in both employment and hours declined by 2.3 percent between the fourth quarter of 1979 and the second quarter of 1980.

Unemployment up among all groups

After edging up in the first quarter, the overall rate of unemployment rose 1.4 percentage points in the second quarter of the year; men, women, and teenagers reported increased rates of joblessness. The jobless rate for men, usually the most cyclically sensitive, showed a marked deterioration earlier than other worker groups. The rate for men rose from 4.2 to 4.7 percent between the end of 1979 and the first quarter of 1980, and surged to 6.4 percent in the second quarter. The rate for women did not begin to rise until the second quarter, when it advanced 0.8 percentage point to 6.5 percent. The jobless rate for teenagers also rose only in the second quarter, jumping 1.8 percentage points to a mid-year 18.0 percent.

The jobless rate for blacks rose more, in absolute terms, than the rate for whites. For each percentage point rise in the white rate, the rate for blacks rose 1.5 percentage points. However, because the black rate was already more than twice as high as the white rate, the *relative* increase in the black rate was smaller than that in the white rate. This produced a narrowing of the ratio between the two rates, an occurrence that is common in the initial stages of recession but that is usually reversed during the recovery period.[3]

The Hispanic unemployment rate was about unchanged in the first quarter of 1980, but moved up 1.2 percentage points to 10.2 percent in the second quarter. The ratio of Hispanic to white unemployment rates fell between the end of 1979 and the middle of 1980. However, in this case, the changes in unemployment rates were about in proportion (that is, there was about 0.9 percentage point of additional Hispanic unemployment for each increment of 1.0 percentage point of white joblessness).

Following are the seasonally adjusted unemployment rates for whites, blacks, and Hispanics in the last quarter of 1979 and the first half of 1980 (data are not yet available for the Hispanic age-sex groups):

	IV	*I*	*II*
White:			
Total	5.1	5.4	6.6
Men	3.7	4.2	5.7
Women	5.0	5.0	5.7
Teenagers	14.0	13.9	16.2
Black and others:			
Total	11.2	11.7	13.4
Men	8.6	9.4	11.8
Women	9.9	9.8	11.4
Teenagers	34.1	35.2	33.2
Hispanic origin:			
Total	8.9	9.0	10.2

Other indicators. Developments in major unemployment indicators between the end of 1979 and second quarter of 1980 included a rise in the jobless rate for blue-collar workers, for workers in manufacturing industries, for full-time workers, and for married men. Among occupations, recession-related unemployment increases in the first half of the year were most visible among sales workers, craft workers, and transport operatives. Among industries, severe increases in joblessness were recorded in construction and durable goods manufacturing.

In the first quarter, the number of persons on layoff (a sensitive cyclical indicator) was above the million mark for the first time since the end of 1977, and rose again substantially in the second. The second quarter level of 1.8 million represented about 23 percent of total unemployment; by comparison, workers on layoff in 1979 accounted for 14.0 percent of total unemployment. New entrants to the labor force declined as a share of unemployment during the second quarter of 1980.

The other widely followed indicators of labor market activity include data on part-time workers and discouraged workers. The number of persons on part-time schedules for economic reasons, sometimes referred to as the "partially unemployed," rose 675,000 in the first half of the year to 4.1 million. After reaching 995,000 in the first quarter, the number of discouraged workers, sometimes referred to as the "hidden unemployed," fell slightly in the second quarter. Increases in the number working part time for economic reasons, moreover, usually lead rises in unemployment. Among discouraged workers, most of the changes occurred among persons citing job-market factors as their reason for discouragement, rather than personal factors.

Developments in two key industries

The general decline in labor market conditions was preceded by troubled times in the housing construction and automobile industries. Construction and auto manufacturing are industries in which changes in production and employment affect the rest of the economy through relatively strong linkages. For example, the building industry is quite obviously linked to the lumber and wood products industry, and in a similar manner, automaking is linked to the production of steel and other metals. The "sensitivity ratio" is a measure of the effect of demand changes for a product on employment in the industry manufacturing that product and in related industries. A study analyzing the employment drop in the last recession established the sensitivity ratios for housing and automobiles at 2.50 and 2.75, respectively.[4] Following are some related industries in which employment is most likely to be affected by demand changes in the housing and automobile industries:

Housing:
- Blast furnaces and steel mill products
- Fabricated metal products
- Railroad and truck transportation

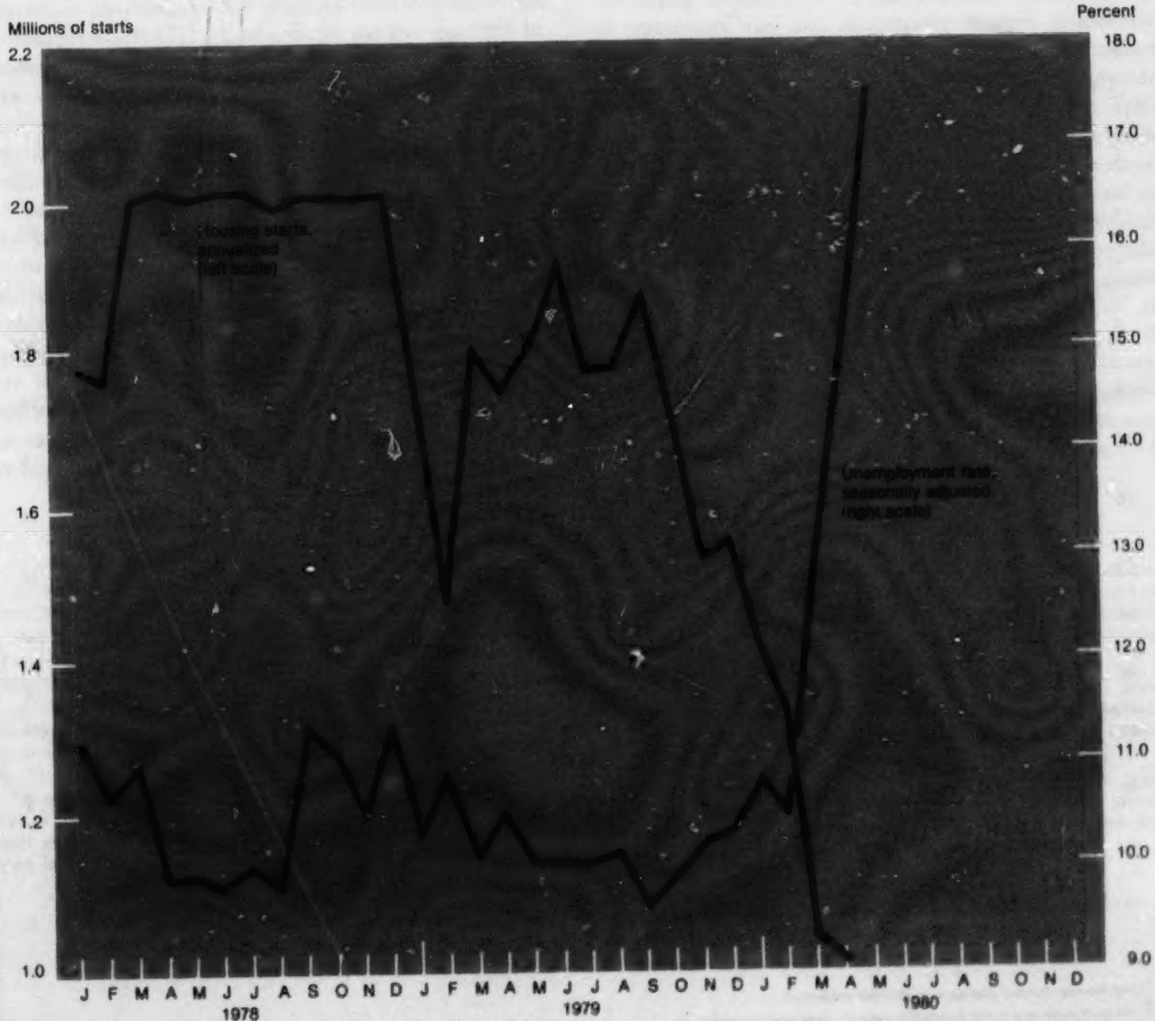
Using construction as an illustration, the sensitivity ratio (2.5 to 1) indicates that for every job lost in the industry there is a total loss of 2.5 jobs (the original construction job plus 1.5 positions in other industries.)

Construction and residential housing. One of the measures of production for the housing market is the annualized rate of private housing units started, as reported monthly by the Bureau of the Census. As chart 2 illustrates, there were signs of weakening in the housing market as early as the beginning of 1979. In each month last year, starts were lower, and in some cases

Chart 2. Housing starts and unemployment in construction, 1978-80



SOURCE: U.S. Bureau of the Census (housing starts); unemployment rate from unpublished data from the Current Population Survey.

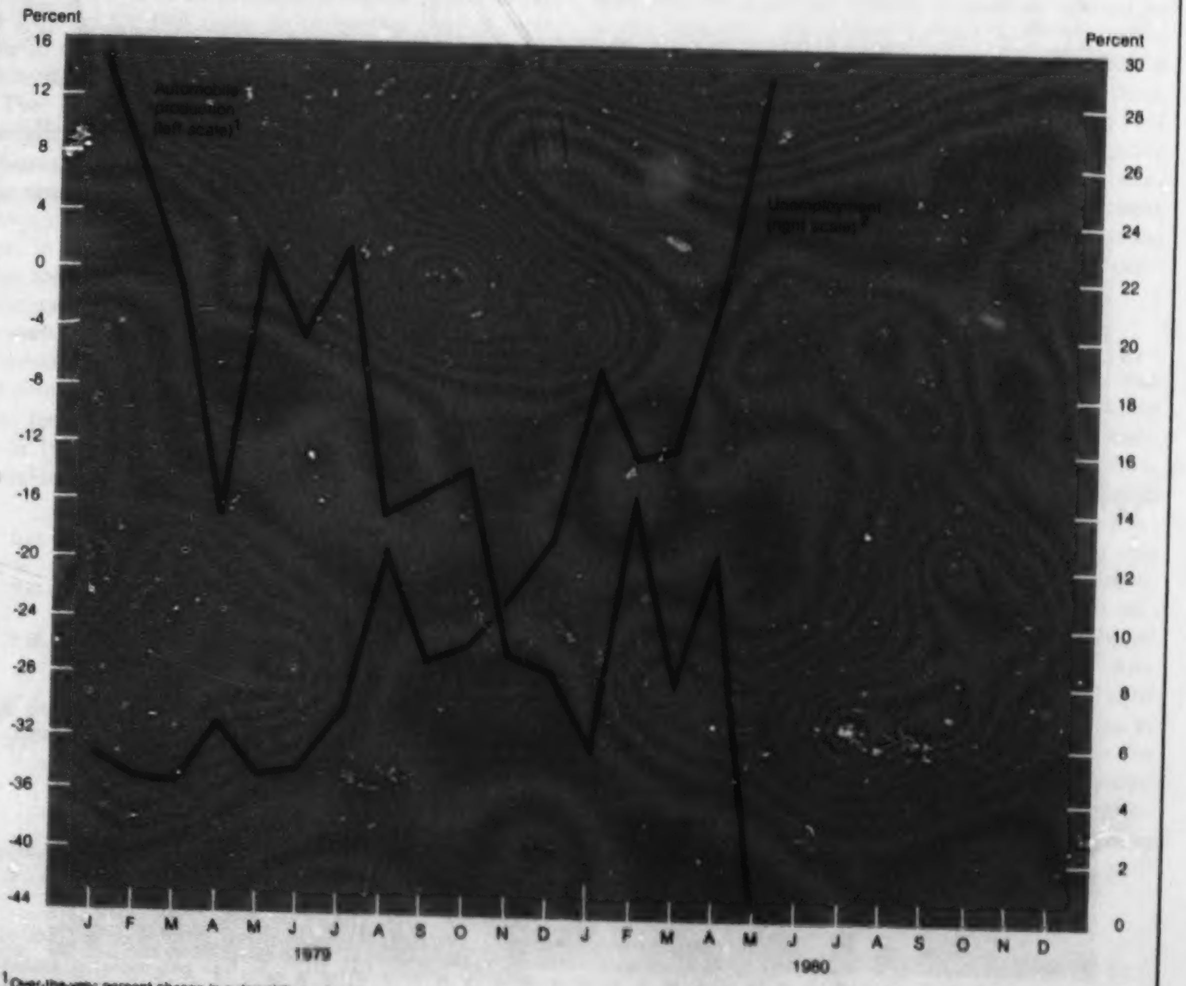
substantially lower, than in the corresponding month of 1978. In the third quarter of 1979, housing starts declined even more quickly, and by mid-1980, housing starts were hovering around the 1 million mark, about half the level of the second quarters of 1977 and 1978.

On a seasonally adjusted basis, payroll employment data for the general building construction industry group (SIC 15), a group that includes the bulk of residential construction activity, showed a great deal of strength throughout 1979, when compared to the previous year.[5] This development reflects the relatively high levels of housing starts in 1978. However, there was a complete stop in the housing industry's employment growth in the fourth quarter of 1979, followed by a sharp contraction in the first 2 quarters of 1980.

Moreover, the unemployment rate for wage and salary workers in the construction industry also illustrated a deteriorating labor market in the housing industry. After dropping in 1977, 1978, and 1979, the jobless rate in construction rose 1.3 percentage points from the last quarter of 1979 to the first quarter of 1980 and then went up 4.9 more percentage points, to 16.3 percent, in the second quarter.

Automobiles. Like housing construction, the automobile sector showed signs of declining somewhat earlier than

Chart 3. Production of automobiles and unemployment in the automobile industry, 1979-80



[1] Over-the-year percent change in automobile production.

SOURCE: Ward's *Automotive Reports* (automobile production, unemployment rate from unpublished data from the Current Population Survey.

the rest of the economy. In addition to being affected by the rising costs of financing consumer sales, the domestic automobile industry has been squeezed by the rising prices of gasoline and other petroleum products and the accompanying rapid shift in consumer demand for smaller cars. Demand for domestic automobiles, as reflected by sales figures, started to weaken in early 1979 in response to those factors. Starting in March 1979, sales were below their year-earlier levels for each of the 16 months up through June 1980. Domestic production started a similar pattern of consistent decline a few months later (August 1979), as manufacturers began to reconcile their marketing, inventory, and production plans to falling demand.[6]

These developments had a profound effect on employment and unemployment in the automobile industry. Payroll employment in the industry (motor vehicles and equipment—SIC 371) fell in each of the five quarters beginning in the second quarter of 1979. The total loss of jobs between the first quarter of 1979 and the second quarter of 1980 has been 300,000, or 29 percent. In the second quarter of 1980, there were 745,000 workers on motor vehicle and equipment makers' payrolls.

Unemployment in the auto manufacturing industry also started to change dramatically in the second quarter of 1979. After rising from 3.2 percent in the first quarter of 1978 (the lowest rate since the historically high rates of 1974 and 1975) to 5.2 percent in the second quarter of 1979, the auto industry unemployment rate jumped 4 percentage points in the third quarter of that year. After a smaller increase in the fourth quarter, the rate rose 5.8 points in the first quarter of 1980 and an additional 8.5 points in the second, to 25.2 percent. (See chart 3.) Between the second quarters of 1979 and 1980, the number of unemployed auto workers rose by a quarter of a million.

Recession verified

The National Bureau of Economic Research, a well-known group of private-sector economists that traditionally establishes business cycle turning points in the United States, announced that the Nation entered the recessionary phase of the cycle in January 1980. Overall, employment remained relatively strong through that first quarter, however, distinct weakenings in the markets for labor in two key industries appeared as early as mid-1979. Employment in automaking peaked in the first quarter of 1979, and the subsequent drops in production and employment have been partly responsible for falling employment in iron and steel foundries, metal stampings, tire and automotive dealers, and service stations. Cutbacks in housing construction, which started in late 1979 and early 1980, have led to employment losses in saw mills, plywood makers, household appliance manufacturers, floor covering mills, and paving and roofing material makers. By midyear, these developments, combined with the generally weaker total demand associated with recession, brought the Nation's total employment down sharply from its record-setting (both as an absolute and as a percent of population) peak of 1979. The unemployment rate rose to the highest point since the early stages of recovery from the 1973–75 downturn. And, after 5 months of the current downslide, several of the leading indicators of marginal employment adjustment, such as the factory workweek, layoffs, and accessions, were continuing to worsen. ☐

The labor force experience of black youth: a review

Jobless rates among black youths have remained far above prerecession levels; regression analysis shows military reductions, population share, and the minimum wage contributed to black youths' problems; jobs programs have helped, as could new efforts that integrate school and work in low-income areas

GEORGE IDEN

The unemployment situation of black youths grew markedly worse in the 1970's. For black teens, ages 16 to 19, this continued a long-term trend beginning in the 1950's. But for older black male youths, ages 20–24, the increase in unemployment of the 1970's was a marked change from earlier patterns.

Since early 1978, the black youth employment situation showed some modest improvement because of relatively more openings in the job market and because youth employment programs were expanded—particularly under the Youth Employment and Demonstration Projects Act of 1977. These gains, however, were not enough to restore the losses sustained earlier in the decade.

Two longer term factors are taking on increased importance in the labor market situation for black youth: first, black youths seem to have been affected disproportionately by the generally unfavorable job market that characterized much of the 1970's. Second, although school enrollment rates for black youths have increased substantially, black students seem to be having a particularly difficult time in obtaining part-time jobs. This, in turn, represents a loss of potential experience and income that may exacerbate future employment difficulties.

A dual situation seems to characterize the experience of black youths in the labor market in the 1970's. Wages of black youths are very close to those of white youths.[1] In addition, some recent research indicates substantial progress during the 1960's and 1970's in closing the occupational gap between white youths and black youths.[2] However, an examination of employment and unemployment indicators suggests that differentials between blacks and whites seem to be widening. Thus, it may be becoming increasingly difficult for a growing proportion of black youths to get jobs at the same time a growing proportion may be getting better jobs.

The elements behind the worsening job market expe-

rience of black youths are investigated in three sections. First, trends in black youth unemployment and employment during the 1970's are examined, with emphasis on the period since 1977.[3] Second, a simple multiple regression model is used to analyze factors affecting teenage employment rates by race, including the effects of overall labor market conditions, supply factors, the minimum wage, and the expansion in youth employment programs after 1977. The third section discusses the increasing school enrollment rate for black youths coupled with extremely low labor force participation rates of young black students. Following this analysis, principal conclusions and policy implications are summarized.

Review of labor market trends

In analyzing the labor market situation of black youths, it is important to focus on employment-population ratios as well as unemployment rates because a large proportion of black youths are not actively seeking a job and therefore are not counted as unemployed. For example, in 1978 the number of unemployed black teenagers was about 381,000. But, if the labor force participation rate had been the same for black as for white teens, there would have been about 500,000 more young blacks in the labor force. In addition, youth labor force participation rates tend to decline during recessions and to increase during business expansions. Thus, changes in unemployment rates understate both the deterioration in the youth labor market during recessions and the improvement during recoveries. For example, the unemployment rate of black teenagers in 1978 was about the same as in 1975—the worst recession year—but the employment-population ratio showed significant improvement.

Trends in unemployment rates and employment-population ratios for black and for white teenagers in the 1970's are summarized in table 1. The most striking thing about this summary is that unemployment and employment indicators for black teenagers seldom improved and frequently got worse, while that was not the case for white teenagers. For example, in the recovery from the 1974–75 recession, the black teenage unemployment rate was actually higher in 1977 than in 1975; not until 1978 did the black teenage unemployment rate decline noticeably. By contrast, the unemployment rate for white teenagers declined 2.5 percentage points by 1977, and by 1978 it approached the 1973 level.

Data from the 1974–75 recession and previous recessions since 1954 suggest that teenage employment—and black teenage employment in particular—is much more affected by the business cycle than overall employment. In addition, the employment of black teenagers continues to fall or fails to rise for several quarters after recovery begins. In the 1975–78 expansion, black teenage employment showed no growth in the first two years.

Unemployment and employment indicators for older black youths, ages 20 to 24, are summarized in table 2 for the period since 1970. These young blacks also are disproportionately affected by the business cycle. However, the increase in their unemployment rate and decline in their employment-to-population ratio during much of the 1970's may reflect more than cyclical influences. There was significant improvement in these indicators in 1978–79, but it is too early to determine if the improvement is more than temporary.

Location. Unpublished Bureau of Labor Statistics data on employment and unemployment of black youths in 1978 show that employment problems for black youths are especially severe in low-income areas of large cities, particularly older cities along the Atlantic coast and in the industrial Midwest. Comparisons of unemployment rates for poverty and other areas understate the true differences in labor force activity because labor force participation rates are significantly higher in areas where average income is above the poverty line. Nevertheless, huge gaps in employment status exist between white youths and black youths regardless of location.

Work force factors. The demographic bulge (in the size of the youth population) has generally been emphasized as an important cause of the increase in teenage unemployment rates in the 1960's. Additional factors such as location, discrimination, inadequate education, and changing characteristics of jobs have been emphasized as causes for the increase in black teenage unemployment.[4] But what factors account for the increase in unemployment rates of black—but not white—males, ages 20 to 24 beginning about 1970? The reasons may include the following:

- The unfavorable job market for entry-level workers in general during the decade—a condition exacerbated by the bulge in the population size of this age group, the end of rising school enrollment rates for white youths, and increases in labor force participation rates of women;
- The decline in the size of the military by about 1 million men in the under age 25 group between the late 1960's and the early 1970's;
- The declining proportion of young black males with family responsibilities;
- Changing requirements for entry-level jobs; and
- The long-term effects of more than a decade of very high unemployment for black teenagers.[5]

In sum, the job market for youths became much more congested in the 1970's compared even with the previous decade. Youths, in general, suffered a decline in earnings relative to older workers. But for some youths, particularly black men, the labor market in the 1970's meant no job rather than one at a lower wage.

Rapid growth in the number of black youths, in conjunction with these labor force factors, has exacerbated the situation. The more rapid growth of the number of black youths compared to the growth in the white youth population would not be a causal factor if barriers such as discrimination, location, and educational deficiencies were not also present.

It may be that labor market indicators would have deteriorated for young black men ages 20 to 24 years in the 1960's, if it had not been for the personnel requirements of the Vietnam War and the exceptionally favorable job market of 1965–69. Changing family responsibilities over time probably also played some role. For example, between 1973 and 1978, the proportion of young black men (ages 20 to 24) in the labor force, who were married living with spouse, declined from almost 40 percent to about 25 percent. If martial arrangements had been the same in 1978 as in 1973 and unemployment differentials among marital groups remained the same, the unemployment rate for the group would have been about 1¾ percentage points lower. However, marital arrangements may be related to unemployment conditions, so that causation runs both ways. In any case, the proportion of young white men married living with spouses also declined during this period but without an increasing trend in unemployment.

Regression analysis

Teenage employment-population ratios, by race, can be analyzed using multiple regression techniques. Employment-population data are used because, with unemployment rates for black youths so high, changes in labor force participation are both hard to explain and of questionable importance.

The model underlying the regression analysis has become fairly standard. The employment-population ratio for the teenage group is strongly related to overall labor market conditions, represented by the unemployment rate for "prime working-age" men (ages 25 to 54). In addition, this relationship was thought to be nonlinear, with teenage employment rates showing a greater response when jobseekers outnumber jobs than when the reverse exists. The reasons for this nonlinearity include a larger supply elasticity for youths compared with the labor force in general and a preference on the part of employers for more mature and experienced workers.

The relative supply of teenagers would also be a relevant factor depending on how readily teenagers may be substitutable for other groups in the labor market and whether the market is free to adjust. Two supply factors are important here: the proportion of teenagers in the population of working age and the size of the armed forces relative to the size of the teenage population. In addition, the level and coverage of the minimum wage could also be a consideration because of possible constraints on the wage flexibility of the youth labor market in response to fluctuations in supply and demand.

Government employment policy, particularly the Youth Employment and Demonstration Projects Act of 1977 (YEDPA), may have had an influence on teenage employment rates. An attempt was made to capture the effect of the recent youth initiatives by including a dummy variable which was assigned a value of 1 for quarters beginning with 1978:1. Enrollments in the youth act programs began increasing very rapidly beginning in 1978:1 and leveled off by mid-1978 at approximately 200,000. In addition, the Summer Youth Employment Program was increased by about 100,000 jobs in 1978 compared with 1977. The additional jobs associated with these programs were disproportionately filled by minority youths.

Finally, a time trend was included to capture other longer term influences. For white teenagers, the trend variable was assigned a value of 1 beginning with the first quarter of 1965, 2 for the second quarter, and so on, and zero before 1965. Although admittedly quite arbitrary, this formulation was chosen because the employment-population ratios for white teenagers apparently began increasing on a long term basis about 1965, as did white teenage labor force participation rates. For black teenagers, the regression time trend was started at the beginning of the period (1954:1) because a perusal of the employment-population series suggested that there might be a negative trend throughout 1954–79.[6]

Using quarterly data for the period 1954:1 through 1979:2, the parameters for the following equation were estimated for black and white teenagers separately:

$$E/P = a + b_1 UH_{-1} + b_2 UL_{-1} + b_3 T + b_4 M + b_5 P + b_6 MW + b_7 D + E \text{ where:}$$

E/P = employment-population ratio (in percent) for teenagers, by race;

UH_{-1} = the unemployment rate of men ages 25 to 54 in excess of 3.4 percent, and zero otherwise, lagged 1 quarter;

UL_{-1} = the unemployment rate of men ages 25 to 54 minus 3.4 percent, when the unemployment rate of that group was equal to, or fell below, 3.4 percent, and zero otherwise, lagged 1 quarter;

T = time trend, beginning with 1954:1 for blacks and 1965:1 for whites (T_2);

M = number of persons in the armed services divided by the teenage population, ages 16 to 19;

P = teenagers, ages 16 to 19, as a percent of the population ages 16 to 64;

MW = minimum wage variable consisting of the basic minimum wage as a percent of hourly earnings, weighted by industry employment and coverage under the law, with a distributed (second degree polynomial) lag over 6 quarters;

D = dummy variable equal to 1 for quarters beginning 1978:1;

E = error term.

The results—summarized in table 3—confirm that youth employment is very sensitive to overall job market conditions. But in addition, they indicate a larger response to an expanding job market when unemployment for the prime working-age male group is below the postwar average, compared with unemployment above the average. In the equation for black teenagers, the coefficient for high unemployment periods (b_1) was quite small and that for low unemployment periods (b_2) quite large—suggesting that the black teenage employment-population ratio does not increase very much until the unemployment rate for prime working-age men gets below 3.4 percent.

In an unfavorable job market, the addition of some job opportunities helps but does not seem to greatly spur employment of black teenagers. After the unemployment rate for prime working-age males declines to the average for the postward period, further expansion of the job market seems to cause more marked improvement. In the 1970's, however, the unemployment rate for males ages 25 to 54 seldom got below 3.4 percent.

The coefficient for the military variable was both large and statistically significant in the equations for black teenagers, but not in those for white teenagers. This suggests that black youths have relatively more difficulty adapting to fluctuations in military personnel needs than white youths.

The population share and minimum wage variables proved to be important for both races, but comparatively more important for blacks.[7]

The results suggest that the recent youth employment programs may have increased the employment rate for black teenagers by about 1 percentage point, although this is not statistically significant at the 95 percent confidence level. The effect of the jobs programs on white teenage employment rates appears negative, but this result also was not significant.

The time trend variable was not statistically significant in the equations for black teenagers; but it was

Table 3. Regression results of factors affecting teenage (age 16 to 19) employment rates, by race, 1954 to 1979

("t" values in parentheses)

Race and sex	Adult male unemployment (t-1)		Time trend		Military personnel level	Population ratio	Minimum wage	Jobs programs	RHO [1]	Constant	R^2
	High	Low	1954	1965							
Black											
Teenagers	0.64 (2.16)	−3.36 (5.72)	0.07 (1.58)		23.56 (1.98)	−2.16 (3.89)	−0.36 (2.99)	0.94 (.86)	0.50 (5.46)	56.43 (8.09)	0.93
Male teenagers	1.51 (4.22)	−2.70 (4.02)			39.35 (4.13)	−1.87 (3.16)	−.43 (4.69)	.91 (.75)	.28 (2.79)	64.64 (8.41)	.95
White											
Teenagers	−1.00 (5.85)	−2.60 (7.52)		.31 (18.56)	−1.56 (.27)	−1.54 (4.63)	−.27 (4.42)	−.42 (.89)	.56 (6.50)	65.38 (15.24)	.97
Male teenagers	−1.20 (5.53)	−3.35 (7.93)		.29 (13.91)	−1.38 (.19)	−1.83 (4.44)	−.34 (4.53)	−.90 (1.22)	.60 (6.47)	77.05 (14.45)	.95

[1] Autocorrelation correction factor.

positive, significant, and rather large in the equation for whites. As a test, the time trend in the equation for whites was started at the beginning of the period (1954:1) rather than the first quarter of 1965. With this specification, the coefficients for the time and unemployment variables were not substantially changed, but that was not the case for several of the other coefficients. Specifically, the coefficient for military became significant and positive, while the coefficients for the minimum wage and population share variables were larger.

In the equations for whites, the sensitivity of some of the coefficients to the specification of the time variable suggests that their magnitudes are especially uncertain.[8] However, this problem was not apparent in the equations for black teenagers, because the coefficient for the time trend was not statistically significant and because omission of the time variable did not substantially affect other coefficients.

The results suggest that the military factor, population share, and minimum wage were approximately of equal importance in accounting for the decline in the employment-population rate for black teenage males during the 1955 to 1970 period—each contributing approximately 6 to 7 percentage points to the decline. However, in 1970–79, the military factor became relatively much more important, accounting for a decline of about 4 percentage points. In the latter period, the minimum wage accounted for only about 1 percentage point of the decline, while the population share had a slightly off-setting effect.

Student workers: a wide racial gap

The racial gap in labor force participation rates for youths is much larger for students than for nonstudents. In October 1977, the labor force participation rate for white teenagers in school was 22.5 percentage points higher than the comparable rate for black teenagers; the racial gap was 13.3 percent for the out-of-school group. (See table 4.)

In the early 1970's school enrollment rates were higher for white teenagers than black teenagers. By the end of the decade, however, the situation had been reversed. Substantially increased rates of school enrollment for black youths and decreased rates for most groups of white youths may "explain" an important part of the widening racial gaps in labor force participation rates and employment-population ratios. Although the gains in school enrollment rates for black youths are impressive, one of the reasons behind the increases is that black youths tend to finish high school at older ages than white youths. Furthermore, poor alternatives in the job market may be a factor influencing young blacks' decisions to stay in school.

Table 4. Labor force participation rates and school enrollment rates of youths by race, 1970 and 1977

[In percent]

Sex and race	Labor force participation rate				School enrollment rate	
	Youth enrolled in school		Youth not in school

Male						
Ages 16 to 19						
Black	26.2	27.6	72.3	77.7	66.6	74.0
White	41.5	49.4	87.3	90.5	75.4	69.1
Ages 20 to 24						
Black	41.3	43.7	90.5	88.8	18.1	27.5
White	52.1	55.7	95.3	95.7	30.9	25.7
Female						
Ages 16 to 19						
Black	22.3	21.9	50.7	56.9	64.1	68.4
White	36.7	45.1	61.4	69.3	66.1	65.2
Ages 20 to 24						
Black	38.9	40.6	60.7	64.6	13.0	21.2
White	51.9	59.2	59.9	70.8	15.5	19.8

Why are labor force participation rates so much lower for black teenagers in school compared with their white counterparts? One basic reason is that there are simply many more students looking for parttime jobs than are available, so the jobs are rationed. The most advantaged students tend to get the jobs. Parents' influence in the community may be especially important in securing part-time jobs for their student sons and daughters. The minimum wage may exacerbate the employment difficulties of black students by reducing the number of jobs potentially available. Discrimination also plays a role, and its existence can be more easily concealed by employers faced with many more jobseekers than needed.

In addition, location may play a role, because part-time jobs for students are concentrated in retail trade,[9] and that sector is, in general, not prosperous in large central cities where many black youths are located. Poorer quality of education available to black youths in inner city schools may also be a substantial handicap in competing for limited job opportunities.

Some observers argue that labor market experience for youths in school is of little consequence and that public resources should be concentrated on youths who are "out of school and out of work." Although that group may well be more disadvantaged than the in-school group, it is also true that some work experience while in school seems to improve job opportunities after leaving school.[10] Moreover, recent black high school graduates tend to have extremely high unemployment rates. The Current Population Survey for October 1978 indicated an unemployment rate of approximately 40 percent for recent black high school graduates, compared with 10 percent for recent white graduates.[11] Thus, less job experience and poor labor market knowledge may partially explain the difficulty of black youths in obtaining post-school employment.[12]

What future course?

Based on the unemployment and employment experience of black youths in the 1970's, the outlook for the early 1980's is not encouraging. In general, black youth unemployment continued to get worse in the 1970's. Although some improvement took place beginning in 1978, it was not enough to make up for losses in the first 7 years of the decade. In 1978, the black youth unemployment rate remained above 40 percent in central city poverty areas and above 30 percent in suburban and rural areas.

One of the most troublesome issues identified in this analysis is that the black teenage employment-population rate is much less responsive to improving job markets when measured unemployment remains above average historical levels. Unfortunately, we seem to be in an era of continually unfavorable job markets—partly as a result of an inflationary environment and partly as a result of very rapid growth in the labor force. According to some analyses,[13] unemployment in 1978 may have been at the lowest noninflationary level now possible, and yet the unemployment rate of men age 25 to 54 was very close to its average for the postwar period—not its average for business cycle peaks. Moreover, most recent forecasts show overall unemployment rising from its 1978–79 plateau of about 6 percent to more than 8 percent in 1980–81. In sum, the gains in black youth employment since 1978 seem likely to be only temporary, given the outlook for a weaker economy and the adverse trend in the labor market for black youths during much of the 1970's.

The size of the armed forces in relation to the size of the teenage group was an important factor affecting black, but not white, teenage employment rates.

The turnaround in the demographic situation should help youth employment rates of both races, but in the case of blacks the improvement seems likely to be small in relation to current employment indicators.

The direct positive effects of the youth employment programs have already been realized by black youths, with additional benefits only if there is a further increase in the scale or effectiveness of these programs. The only major recent policy innovation that has not yet been phased in is the targeted jobs tax credit passed by Congress in 1978. The Administration has recently proposed a modification and expansion of youth programs, but according to the present time table, it would not have much effect until after 1981. However, both efforts reflect some commitment to resolve the problems of black youth employment.

The case for doing more to reverse the trends in black youth employment and unemployment includes the following: the extreme concentration of serious youth employment problems—geographic and racial—has especially serious implications because such an environment often undermines productive or socially constructive behavior. The problems seem to be getting worse, and there is some evidence to suggest that the employment problems of teenagers become employment problems of young adults. Moreover, black youth unemployment probably can be reduced without increasing the inflation rate.

Finally, the very low employment rates for black students—and the probability that work experience during school provides invaluable job market information—suggests the need to target employment programs to help low-income youths in school, as well as those out of school and out of work. Several of the policy instruments for this kind of initiative are already in place; for example, the provisions in Title IV of the Comprehensive Employment and Training Act, which were designed to encourage the cooperation of local school systems, and the targeted jobs tax credit. Also, the Administration's recent proposals imply close cooperation between CETA, the public schools, and the private sector. However, these kinds of policies may be especially difficult to implement successfully because they require a high degree of commitment and cooperation. □

Wachter, "The Demographic Impact on Unemployment: Past Experience and the Outlook for the Future," in *Demographic Trends and Full Employment*, National Commission for Manpower Policy, Special Report No. 12, December 1976; and *Economic Report of the President*, January 1979, p. 118.

Benchmark revisions

Establishment statistics published by the Bureau of Labor Statistics are based on a monthly survey of 160,000 business establishments and government units. Once a year, these survey statistics are adjusted to benchmarks of complete counts. The counts are derived from unemployment insurance records.

The data in tables 8-20 of the Current Labor Statistics section of this issue of the *Monthly Labor Review* have been revised as a result of such benchmark revisions. The tables also reflect revised seasonal factors to incorporate seasonal experience through March 1980.

An article discussing the benchmark revisions and their effect on the establishment statistics appears in the July issue of the BLS periodical, *Employment and Earnings*.

Women in domestic work: yesterday and today

A century ago, half of all wage-earning women were private household workers; in 1979, fewer than 3 percent were so employed; today's black domestic is likely to be a middle-aged cleaner or servant; a white domestic, a young babysitter

ALLYSON SHERMAN GROSSMAN

Private household workers—a group that consists of cleaning workers and servants, childcare workers, housekeepers, cooks, and launderers—continue to dwindle in number. Domestic work is viewed more and more as a low-skill, low-status occupation, and young women, especially black women, are increasingly shying away from it. Today, domestic workers, who tend to be older women with relatively little education, often receive less than the minimum wage. This article provides a historical overview of private household workers and a close look at their status today. Because 98 percent of all private household workers are women, this article focuses exclusively on them.

The past: domestics predominate

A century ago, private household work[1] was the predominant occupation of all gainfully employed women and girls 10 years old and over. Always a female occupation, in 1870, domestic work accounted for more than half of all female wage earners. (See table 1.) While native-born white women tended to shun this occupation which did not require formal education, experience, or well-developed skills, it was an important source of income for many immigrant and black women.[2]

During the 40 years between 1870 and 1910, the number of private household workers nearly doubled—from 960,000 to 1.8 million—as a result of both a steadily growing supply of labor and an ever-increasing demand. A great influx of immigrants had entered the country, and domestic service was the only type of employment available to many. These newly arrived women often replaced other household workers, particularly native-born white women, who were leaving their jobs for a variety of reasons, such as marriage, childbirth, or work in other occupations. At the turn of the century, private household work required living in the employer's residence, and such service was often terminated, or at least interrupted, when a woman married or had a child. During this period, the rapid industrialization

---

Allyson Sherman Grossman is an economist in the Office of Current Employment Analysis, Bureau of Labor Statistics.

and concomitant urbanization of the country gave rise to an expanding number of middle and upper class families who wanted and could afford household help. In fact, the demand for private household workers far outstripped supply.

The number of private household workers declined between 1910 and 1920, as immigration fell and child labor diminished. Proportionately more immigrants from Russia, Poland, and Italy were entering the country during this period, and they were less inclined to be domestic workers than the women from Germany, Ireland, and Scandinavia who had been in the forefront of earlier waves of immigration. Also, young girls age 10 to 15, who formerly had been a source of domestic workers, were increasingly unavailable, as child labor came under attack and compulsory education spread. In addition, the continued urbanization of the country and the onset of World War I altered the focus of female employment. More and more women worked at professional (teaching and nursing), clerical, manufacturing, and sales jobs, so that private household workers accounted for a declining share of female workers.

Yet, demand continued to be strong, as domestic work was viewed by some employers as providing enviable opportunities to women. As one female author discussed in relation to the dearth of such workers in 1915:

> Work in a private house is infinitely more desirable, from the point of view of the influence of one's surroundings, than daily labor in a factory or store. The variety of domestic duties, the freedom of moving from one room to another, or sitting or standing to do one's work, are much to be preferred to the work that compels the worker to stand or sit in one place all day long.
>
> If it be admitted, then, that housework is in itself a desirable and suitable occupation for women who must earn their living by manual labor, it cannot be the work itself, but the conditions surrounding it that make it so distasteful to the modern working woman.[3]

Table 1. Private household workers as a proportion of all employed women, selected years, 1870–1979

[Numbers in thousands]

Year	All employed women	Private household workers	
		Total	As a percent of all employed women
1870	1,836	960	52.3
1880	2,647	1,078	40.7
1890	3,915	1,433	36.6
1900	5,319	1,526	28.7
1910	8,076	1,784	22.1
1920	8,550	1,360	15.9
1930	10,752	1,909	17.8
1940	11,178	2,277	20.4
1950	17,340	1,459	8.4
1960	21,874	1,943	8.9
1970	29,667	1,518	5.1
1971	29,875	1,449	4.9
1972	31,072	1,403	4.5
1973	32,446	1,330	4.1
1974	33,417	1,201	3.6
1975	33,553	1,141	3.4
1976	35,095	1,095	3.1
1977	36,685	1,123	3.1
1978	38,881	1,135	2.9
1979	40,446	1,062	2.6

SOURCES: *Historical Statistics of the U.S. Colonial Times to 1970,* Bicentennial Edition Part I (U.S. Bureau of the Census, 1975).

Employment and Training Report of the President (U.S. Department of Labor, Employment and Training Administration, 1979); and Alba M. Edwards, *Sixteenth Census of the United States: 1940, Population Comparative Occupation Statistics for the United States, 1870 to 1940* (U.S. Bureau of the Census, 1943).

The number of domestic workers rebounded to nearly 2 million between 1920 and 1930, in part, because immigration again accelerated and women more inclined to household work were entering the country. However, other types of employment were growing even faster, and domestic work continued to lose ground as a major source of employment for women. By this time, the nature of private household work had changed, evolving into a job much like any other: the employee lived independently of the employer.

The changing racial composition of the occupational group was a primary force behind this evolution. By the end of World War I, the number of white women in domestic service had dropped substantially. At the same time, black women—who had been concentrated in household work in the South—started migrating in great numbers to Northern cities. They began taking the places of white women who left the occupation for marriage or for other jobs that were increasingly available.

Black women, regardless of marital status, worked outside their homes to a much greater extent than white women. The Department of Labor's Women's Bureau in 1920 reported ". . . it is a well-known fact that most Negro women must continue as breadwinners practically all their lives, marriage rarely meaning a withdrawal from the wage earning ranks."[4] Live-out jobs allowed married black women to work and still raise families of their own. Because private household employment was, in many cases, the only type of work open to them, black women began to account for a growing proportion of domestic workers.

Nevertheless, the high point for private household work as a major employer of all women had long since passed. Immigration had peaked years before, and World War II and its aftermath wrought tremendous changes in American society and the nature of work performed by women. By 1950, fewer than 1 of 10 employed women were private household workers. More recently, with the rapid expansion of the female labor force, this proportion has dropped further.

The present: numbers declining

At the beginning of the 1970's, there were 1.5 million female private household workers, and they accounted for 5 percent of all employed women. By the end of the decade, the number of domestics had fallen to slightly more than 1 million, or less than 3 percent of all female workers.[5] Both a slackened demand for this type of employee and a diminished supply contributed to this drop. For instance, along with the advent of smaller families, continued improvements in household technology eliminated many of the time-consuming, tedious, and difficult tasks associated with running a home. At the same time, increased employment opportunities in other fields, heightened educational attainment (which would provide workers with skills to obtain other types of jobs), and greater availability of public assistance may have hastened the departure of women from this field.[6]

The exodus was more pronounced among black than among white women. While the number of white women dropped significantly from 1970 to 1975 and then plateaued, the number of black women has fallen steadily. By 1979, 45 percent fewer were working in this occupation than in 1970. As the following tabulation shows, in March 1979 very few black women under age 35 worked as domestics:

	Domestic workers (thousands)		
	March 1970	*March 1975*	*March 1979*
Total, 16 years and over	1,649	1,217	1,093
White	974	730	733
Black	633	480	345
Other	42	7	15
Total, 16 to 34 years	599	477	451
White	476	411	417
Black	113	64	30
Other	10	2	4
Total, 35 years and over	1,050	740	642
White	498	319	315
Black	520	416	315
Other	32	5	12

As a result, the racial composition of this occupational group changed from 38 percent black in 1970 to 32 percent black in 1979. Because the basic demographic characteristics of black and white private household workers differ substantially, the following sections focus separately on the two groups.

Black women. Black women employed as domestics in 1979 were older and less educated than black women workers overall. The vast majority worked as cleaners and servants. Many maintained their own families, and their employment provided a major share of their families' support.

Table 2. Selected characteristics of private household workers, by race, March 1979

[Numbers in thousands]

Characteristic	Total	White	Black
Total, 16 years old and over	1,093	733	345
Employment status:			
Employed full time	336	237	94
Employed part time	757	495	251
Unemployed	50	24	26
Unemployment rate (percent)	4.4	3.2	7.1
Age:			
16-24 years	309	292	14
25-34 years	142	125	16
35-44 years	121	65	54
45-64 years	369	169	192
65 years and over	152	82	69
Median age (in years)	42.9	31.0	54.2
Marital status:			
Never married	329	270	53
Married, husband present	450	310	135
Married, husband absent	86	24	60
Widowed	157	89	65
Divorced	72	40	32
Median years of school completed:			
Total	10.9	11.3	9.5
16-44 years	11.5	11.6	10.5
45 years and over	9.5	10.2	8.8
Median earnings, 1979:			
Hourly earnings of those paid by the hour	$2.44	$2.13	$2.68
Usual weekly earnings of full-time wage and salary workers	$89	$80	$110

NOTE: Due to rounding, some components may not add to totals.

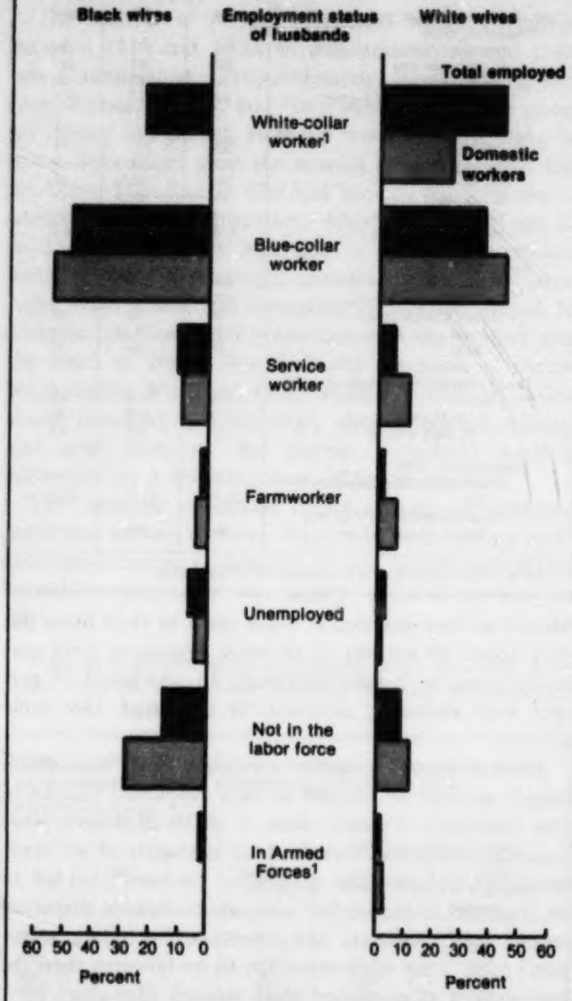
In March 1979, more than 3 of 5 black women in private household work were between the ages of 45 and 64 years, and an additional 1 of 5 were over age 65. Most had been married at some point in their lives, but only about 40 percent of all black domestics were currently living with their husbands; an additional 45 percent were widowed, divorced, or separated. (See table 2.)

Married black domestics were less likely than black female workers in general to have employed husbands. The husbands of fewer than 7 of 10 domestics were working, compared with 8 of 10 husbands of all black employed women. The domestics' husbands tended to be clustered in blue-collar jobs, about equally dispersed among craft, laborer, and operative (including transport) jobs. They were more apt to be laborers than the husbands of all employed black women. (See chart 1.)

Many black women may have stayed in private household work because they are educationally disadvantaged. As a group, black domestics averaged 9.5 years of school in March 1979, with those over age 45 having completed less than 9 years. The median for all black female workers was 12.4 years. Thus, without the schooling or training to meet the requirements of other jobs in today's labor market, many women may be unable to leave household work.

Like most domestic workers, black household workers typically work part time. In March 1979, 7 of 10 reported that they were employed fewer than 35 hours per week. The intermittent nature of the work and the advanced age of many of the women in this group obviously contribute to the high proportion of part-time em-

Chart 1. Employment status of husbands of domestic workers and other employed wives, March 1979



[1] No black domestic workers with husbands in this category.

ployees. Only about 1 of 6 black domestics reported that she worked all year, full time in 1978.

About 25 percent of all black private household workers maintained their own families, and an additional 30 percent were married to men who were out of the labor force. (Of course, because black domestics are older, many of their husbands may be retired.) As a result, these women may be providing a great share of their families' support.

The earnings of private household workers are extremely low by any measure. Although most have been eligible for coverage by minimum wage provisions of the Fair Labor Standards Act since 1974,[7] a large amount of noncompliance with the law is apparent. For instance, in 1974, covered black household employees averaged slightly over $2 per hour. However, 45 percent of those eligible for the minimum wage earned less than the $1.90 hourly rate prescribed by law.[8] Reasons for this apparent noncompliance include: ignorance of the law among some employers and employees; a willingness on the part of some employees to work for less than the legally required minimum in order to have a job; and errors by workers in reporting their wages and perquisites.[9]

As the 1970's closed, the earnings of private household workers remained far below average. In 1979, median earnings for all black women paid by the hour were $3.60; in contrast, 7 of every 10 black domestics earned the minimum wage of $2.90 or less. Black private household workers who were full-time wage and salary workers—slightly more than one-quarter of the total—earned $110 weekly, about one-third less than the median for all full-time black female wage and salary workers.

Despite perquisites—such as lunches and transportation—that some private household workers receive, despite payments in kind, and despite the underreporting or nonreporting of income by some,[10] many domestics are living at the subsistence level. Almost 50 percent of the black women who maintained families and who reported private household work as the occupation at which they worked the longest were below the poverty level in 1978 (the latest year for which poverty data are available). The same was true for half of the black women who did not have any immediate family responsibilities.[11]

White women. The situation for white private household workers was entirely different. As shown in the following tabulation, white women were heavily concentrated in childcare work in 1979:

	Annual averages		
	Total	*White*	*Black and other*
Total (percent)	100.0	100.00	100.00
Childcare workers	43.7	60.2	10.5
Cooks	2.4	1.5	4.0
Housekeepers	8.9	7.6	11.6
Launderers	.6	.4	9
Cleaners and servants	44.4	30.3	73.0

A large component of these childcare workers were youthful babysitters whose social and demographic characteristics were overwhelmingly represented in the composite portrait of white household workers.

Fitting the babysitter pattern, nearly one-third of all white women working in this occupation in March 1979 were never married and under age 25. Because more than half had to balance employment with school attendance, most worked part time, earning only a few hundred dollars in 1978.

The demographic characteristics of the remaining white private household workers were significantly different from those of their black counterparts. On average, they were younger, better educated, and less likely to maintain their own families. In fact, only 1 of 10 white domestics maintained her own family.

About 40 percent were between 25 and 44 years of age. Overall, they had completed an average of 11.9 years of school. A larger proportion—59 percent—were married. Their husbands were employed to a greater degree than were the black husbands, and white husbands were far less likely to be out of the labor force. Blue-collar work was, again, the most prevalent type of employment of the white husbands, although not to the extent of the black husbands. The spouses of white private household workers were much more likely than the blacks to be white-collar workers. However, their proportion was far below that for husbands of all white female workers. (See chart 1.)

In terms of employment status, most of the white domestics were part-time workers; fewer than 10 percent worked all year full time. Median hourly earnings in 1979 of those paid by the hour were about $2.15, with 4 of 5 earning less than $2.90. It should be noted, however, that this median, which was lower than that of their black counterparts, was greatly influenced by the earnings of large numbers of youthful babysitters who were not subject to the minimum wage. White domestics who were full-time wage and salary workers—about 30 percent of all white private household workers—earned $80 weekly, more than $100 below the average for all white female full-time wage and salary workers.

The future: will demand increase?

The nature of household work may change in the years to come. As more commercial enterprises enter the field, domestic workers may find themselves employees of cleaning businesses. As such, they would be subject to the rights and privileges of other workers, such as more rigorous compliance with minimum wage and social security requirements. In addition, the 1980's may witness an upsurge in the demand for private household workers. As greater numbers of women are employed outside their homes, they may seek to substitute paid labor—either from individuals or from businesses—for the work they previously performed in their own homes.

Moreover, efforts have recently been undertaken to upgrade the status of private household workers. Some of this group's needs were included in *The Spirit of Houston*, the official report in 1978 of the National Commission on the Observance of International Women's Year.[12] Also, the National Committee on Household Employment is trying to organize domestic workers throughout the country.[13] This organization, among others, is striving to change the image of domestic workers in both the employee's and the employer's view. By making both parties aware of their legal rights and responsibilities and by emphasizing that household work can be a career with business and professional aspects, the committee hopes to aid private household workers gain greater returns to their labor market experiences. ☐

Vinyl chloride protection: less costly than predicted

CHARLES R. PERRY

The battle over the permanent Federal standard for permissible levels of worker exposure to vinyl chloride was beset with predictions of dire economic consequences which have become commonplace in the standard-setting process. Such consequences clearly have not come to pass, a fact which prompted some to conclude that the industry "cried wolf."[1] That conclusion, strictly speaking, is not justified. But, justified or unjustified, it has had the effect of tempering the industry response to other proposed regulations.

The permanent standard initially proposed by the Occupational Safety and Health Administration (OSHA) called for a level of "no detectable" exposure to the cancer agent. The industry responded that such a standard "is not technologically feasible and, if adopted, would shut down the industry."[2] Interestingly, this claim was supported by the conclusion of a feasibility study, commissioned by OSHA.[3] The consequences of a possible industry shutdown were detailed in a separate study which indicated that $65 to $90 billion in Gross National Product and 1.7 to 2.2 million jobs were dependent on the production of polyvinyl chloride (PVC) resins.[4]

The industry argued for a standard which would set a time-weighted exposure limit of 10 parts per million (PPM) for polyvinyl chloride resin plants and 5 ppm for vinyl chloride monomer (VCM) plants,[5] based on feasibility considerations. Organized labor endorsed the "no detectable level" standard and disputed the infeasibility of such a standard. The results of its own feasibility study forced OSHA to withdraw from the no detectable level standard and to adopt in its place a 1 ppm standard. The industry challenged both the necessity for and feasibility of this stringent limit in the courts with a notable lack of success, particularly because the court of appeals specifically ruled that:

> the secretary is not restricted to the status quo. He may raise standards which require improvements in existing technologies or which require the development of new technology. . . .[6]

The actual economic consequences of this technology-forcing standard for the viability of PVC plants and the availability of jobs in those plants were remarkably modest. A few older PVC plants were shut down, in whole or substantial part, because of the projected cost of bringing those facilities into compliance with the requirements of the standard. These shutdowns resulted in the loss of about 325 million pounds of production capacity and 375 jobs—approximately 5 percent of the industry total. Much of the credit for the modesty of these adverse effects now is attributed by the industry to the reasonableness of the standard itself, as is evident in the following confidential statement of one company representative:

> The OSHA–VCM program was, in the end, a real success story for both OSHA and the VCM–PVC industry. By fighting the "absolute zero" concept originally proposed, industry achieved a more practical 1 ppm standard that allowed it to continue to operate and grow. And, apparently the standard has protected the workers . . . so at least in this case we have a government regulation that has been practical and beneficial to all concerned.

The vinyl chloride standard may not have been catastrophic for the industry, but it was expensive. The first public estimate of the cost of compliance with the 1 ppm standard indicated that the industry would have to invest $200 million (excluding development costs) in im-

---

Charles R. Perry is an associate professor of management and industrial relations at the University of Pennsylvania, Philadelphia, Pa. The title of his full IRRA paper is "Safe and Healthful Working Conditions: The Case of Vinyl Chloride."

mediate process improvements to satisfy the requirements of the standard.[7] The VCM–PVC industry actually invested about $130 million in such process improvements to bring existing production facilities into compliance with the standard. More than 90 percent of this total was accounted for by PVC plants, which employ only about 75 percent of the workers in the industry.

The apparent $70 million cost "saving" recorded by the industry is an attractive focus of attention but in no way offsets the $130 million actually invested in compliance with the standard. It is difficult to identify the sources of the saving without knowledge of the basis of the original $200 million cost estimate, but three possibilities deserve note. First, part of the savings may be attributable to the decision to close rather than modify some older PVC plants. Assuming that these plants had the most acute and expensive compliance problems, they may well have accounted for as much as 10 percent of estimated compliance cost, although they represented only 5 percent of PVC capacity, and for as much as $20 million of the $70 million saving. Second, part of the savings may have stemmed from miscalculation of the significance of the relative cost advantage of VCM facilities in complying with the standard. For example, there was an almost $4,000 per worker difference between average compliance cost for PVC and for VCM–PVC plants which, if not accounted for in industry cost projections, would have added another $25 million to those estimates. Finally, the industry was able to find more efficient means to achieve compliance than were foreseen at the time the standard was adopted. The largest producer in the industry reported it had been able to reduce its projected $42 million compliance cost by 10 to 15 percent through technological developments.[8] If other producers were able to realize similar economies, the total savings for the industry would have been another $25 million.

Compliance with the vinyl chloride standard entailed incremental operating as well as capital costs. Data on incremental operating costs are limited, but the data which are available suggest that compliance probably cost the industry close to $10 million per year or $100 million in present value terms, assuming a 10 percent interest rate and infinite time horizon. Approximately 70 percent of this incremental operating cost was attributable to added activity and staff in two areas—exposure monitoring and equipment maintenance.

The incremental operating costs associated with compliance are noteworthy for three reasons. First, they were not included in public estimates of compliance costs. Second, they were sizable both in absolute amount and in relation to the capital costs of compliance. Finally, they appear to have been primarily a product of exposure control, *per se*, rather than the more peripheral requirements of the standard such as recordkeeping or medical surveillance.

The incremental capital and operating costs associated with compliance constitute the most visible dimension of the economic impact of regulation. A much more subtle and surprising economic impact of the vinyl chloride standard was a significant reduction in effective production capacity and output per man-hour in the industry.

Compliance with the exposure limits set by the standard required substantial changes in work procedures in the industry. These changes resulted in less efficient utilization of existing equipment and manpower, which lowered effective capacity by approximately 15 percent. The actual loss of product and productivity immediately after the standard became effective was slightly less than 15 percent because there was some temporary excess capacity in the industry. Over the longer run, however, the loss of product and productivity in then existing facilities has approached the full 15 percent for two reasons. First, industry sales generally have been capacity limited and second, little progress has been made in eliminating the need for modified work procedures which limit capacity.

The incremental capital and operating costs for compliance with the vinyl chloride standard represent the equivalent of a $23-million increase in annual production cost. That $23 million, in turn, is the equivalent of a $3,000 per year or $1.50 per hour wage premium for the approximately 7,000 workers employed in the VCM–PVC industry. Assuming average hourly compensation of $10 for those workers, the OSHA vinyl chloride standard mandated a 15 percent increase in effective wage rate in the industry. That 15 percent increase coupled with a 15 percent drop in productivity suggests that compliance resulted in a 35-percent increase in unit labor costs. Labor costs, however, are only a small percentage of total costs in the VCM–PVC industry and probably account for no more than 10 percent of total operating costs. Thus, OSHA regulation added no more than 3.5 percent to the cost of PVC resins—about $.005 per pound. Assuming production from then existing facilities of 4.5 to 4.8 million pounds, the cost to consumers would be about $23 million per year. ☐

A view of the costs and benefits of the job safety and health law

RICHARD E. GINNOLD

A major issue in criticism of the Occupational Safety and Health Administration's enforcement of the Occupational Safety and Health Act has been the alleged onerous increases in costs of production. Industry has raised the issue in standards hearings, in contesting penalties, and politically. Not only does OSHA impose high costs, say critics, but the law provides few or no benefits. Opponents of this reasoning have argued that a select minority of workers bears risks so that the general public can consume. To balance worker protection against costs to the consuming public is immoral and inequitable.[1]

While some courts have required OSHA to consider economic feasibility, a recent D.C. Circuit Court decision on the cotton dust standard clearly states that economic feasibility tests were purposefully left out of the law, in contrast to other environmental laws. The court says:[2]

> In the Clean Air Act, for example, Congress required the Environmental Protection Agency (EPA) to perform a "cost-benefit analysis" . . . Some Congressional acts require a showing of 'unreasonable risk' prior to regulation. The legislative histories of these acts have led the courts to construe this provision to require regulatory agencies to balance costs and benefits of proposed action. In the OSH Act, in contrast, Congress itself struck the balance between costs and benefits in the mandate to the agency. Section 6(b)(5) unequivocally mandates OSHA to:
>
> > 'set the standard which most adequately assures, to the extent feasible, on the basis of the best available evidence, that no employee will suffer material impairment of health or functional capacity.'
>
> In contrast to the acts for which Congress contemplated a cost-benefit requirement, the legislative history of the Occupational Safety and Health Act contains no reference to this kind of economic analysis.

This view contrasts with the 5th Circuit view in the benzene cases now before the Supreme Court. If the D.C. Circuit view prevails, it will greatly assist OSHA in sustaining other urgent but costly health standards.

High costs imposed?

Regardless of the legal position, the cost issue is of practical importance. How do the costs impact on the economy or individual employers? What are the corresponding benefits? Concerning overall costs, it appears they have been greatly exaggerated. Brookings Institution economist Edward Denison did a special study of the impact of environmental costs on growth.[3] He found that all environmental impacts from 1967 had lowered productivity 1.8 percent by 1975.

However, only one-quarter of this, or .42 percent, was due to health and safety regulations. Furthermore, .09 percent was due to auto safety, .24 percent was due to mine safety, and only .09 percent to one-tenth of one percent of total productivity loss was due to OSHA. As Denison points out, this was a measure of gross cost alone, and he did not attempt to measure the health benefits resulting from the costs measured.

Another recent source is a study by the Business Roundtable[4] which measured the incremental costs of environmental regulation by 48 companies making up over one-quarter of the total manufacturing sector (among others) with over $25.8 billion in capital expenditures and $16.6 billion in corporate after-tax profits. These companies reported that the added cost of business due to six Federal regulatory agencies in 1977 was $2.7 billion. The costs of EPA compliance made up 70 percent of the total, which the industry estimates thus far have not caused significant economic problems. Also, as Nicholas Ashford and others have argued,[5] frequently OSHA standards speed up the normal replacement cycles and cause the industry to install a possibly more productive and competitive technology than it was using previously. Costs related to job safety and health were $184 million, or 7 percent of the total. The companies also reported that most of this expense was incurred in earlier years. The McGraw-Hill survey of business safety and health expenditures shows planned spending of $4.9 billion in 1979, as compared with $2.5 billion in 1972. This is a large rise, but not too much more than the rise in producer prices.

There still is the question of long-term economic impacts, effects on worker productivity and employment effects on industries which have refitted or changed production methods to comply with job safety and health requirements. It is important to have a better idea of these costs. Also, given the standard, how long does it

take to get it fully enforced in all firms? More detailed impact studies should be done for individual firms applying new standards or complying with a controversial standard, for example, noise control and ventilation.

The impression that compliance costs have not been onerous is also confirmed by a number of cases cited by Basil Whiting, OSHA deputy assistant secretary, where the costs of industry compliance with new health standards—vinyl chloride, acrylonitrile, beryllium—turn out to be far lower than initial projections indicated.[6] It should be mentioned that in most of these cases there has not been a thorough followup study, after the standard has taken full effect, looking at both economic and health impacts. These studies are obviously needed.

Because of the uncertain knowledge of firms faced with expensive compliance, there should also be an OSHA hotline and clearinghouse of information on technical and economic feasibility. Case studies of successful compliance efforts could be obtained from Federal and State compliance officers, State consultants and the National Institute for Occupational Safety and Health. This would greatly assist OSHA officers in informal conferences with employers and in handling contested cases. It could also be used by employers and unions dealing with specific compliance problems.

If we ask workers in hazardous jobs about the impact of the Occupational Safety and Health Act and its benefits, there will be no question. The improvement in ventilation, noise reduction, machine guarding, and management's willingness to correct hazards is much greater than before OSHA. Workers can get information on toxic substances for the first time. Yet this anecdotal evidence needs more concrete supporting data. John Mendeloff calculated a possible benefit of $380 million from injury reduction, projected nationally.[7] A recent report estimated the law's injury and illness reduction benefits at over $5 billion, exceeding current projected industry costs for safety and health.[8]

However, we can't even quantify the impact in most areas, let alone attach benefits to it. To go further in measuring benefits, it is necessary to have much more microresearch into injury rate data and case studies of particular firms, industries, and standards to build the base for more global estimates.

Maximizing OSHA's impact

The foregoing discussion indicates that the law has not had the exaggerated cost impact its critics have charged and on balance has had some measurable positive impacts. Yet, it is important and possible for OSHA to produce more tangible impacts on the injury and illness problem. There are several areas of needed action.

Injury and fatality data are being used widely by OSHA's critics to show negative effects. OSHA and the Bureau of Labor Statistics should quickly investigate the anomalies mentioned earlier and also determine to what extent outside factors like workers' compensation improvements are causing the stability or rise in injury rates and how to obtain a rate which more truly reflects changes in job hazards.

As nationwide surveys show,[9] only 20 to 25 percent of all workers are exposed to serious safety and health hazards and just 16 percent of the workers surveyed had experienced an injury or illness in the past 3 years. Only 7 percent felt their injury or illness was a serious problem. The same concentration is seen on the employer side. Approximately 125,000 employers with more than 20 employees have above average injury rates. In the State of Washington, 10,000 employers have almost all the injuries. Even allowing for some statistical turnover of employers from year to year, it is clear that safety and health risks are a priority issue for a minority of employees and employers. OSHA should be directing its entire focus at this group (granted the need to respond to complaints from workplaces missed by the general rule).

Once high hazard employers are identified, their injury and illness experience should be analyzed and related to needed control measures. Where codes are lacking, general duty guidelines should be made available. The targeting emphasis should not stop with inspections, but should be incorporated into the focus of OSHA-funded State consultation programs and "New Directions" education programs. OSHA and its related agencies should all be thinking in terms of a specific injury reduction target—say, 10 percent per year—and making that the focus of activity. There would be some conflicts between this goal and some natural increase in compensation claims from increased awareness and past exposure, but this could be kept separate.

Many of the fastest growing injury causes are not covered by standards, such as back injuries and tendonitis. With a decline in physical conditioning and more women in the labor force, many tools, machines, work procedures, and lifting customs are increasingly hazardous. OSHA now has no standards in these areas, even though some OSHA offices have been citing job design problems in cases where large numbers of "carpal tunnel syndrome" (a wrist nerve deterioration) are seen. OSHA should establish general duty guidelines and practical control measures for citing the most frequent physical stress problems, for example, excessive lifting, job designs which require twisting under load, improperly designed tools and chairs, and standing for long periods on hard floor surfaces.

There are many other issues which could be discussed. OSHA needs to expand the use of general duty citations to overcome the delay in standard-setting. Labor Department lawyers and Occupational Safety and

Health Review Commission judges see the use of general duty as a litigation problem, but 90 percent of OSHA citations are settled in the field and a strongly based general duty clause is worth as much as a standard. □

Rise of pensions and social security created alternating goals for unions

BRUNO STEIN

Private pensions and social security retirement benefits easily accommodated each other from the late 1940's until the mid-1960's. Afterwards, the rapid growth in social security benefits altered the role of pension retirement systems and cast doubt upon their future, much to the distress of segments of the pension community.

The important breakthrough on the pension scene occurred in the late 1940's at the bargaining table, when unions began to demand pensions. At the time, social security retirement benefits averaged $29 per month and replaced about 20 percent of the median wage as it was in the year prior to retirement.[1] In view of these low benefits, unions had found an important bargaining issue. But income taxes were now a factor. Before World War II, most workers were below the income tax threshold, but afterward the tax became a wedge between a worker's gross and net incomes; pensions act as a tax shelter. Initially, the tax advantage to workers may have been less obvious in pensions than in other fringe benefits. However, the advantages increased with age, income, and inflation.[2]

Pension coverage grew sharply in the union sector, and spilled over into the nonunion sector. In 1950, 9.8 million workers had coverage; 10 years later, 18.7 million. After that, growth stemmed more from the increasing number of workers in businesses with existing plans than from the inauguration of new plans. By 1975, coverage had reached 30.3 million workers.[3]

Although the low level of social security benefits may have caused the rise of pensions, those benefits began a dramatic upward march in 1970. Between 1970 and 1977, nominal benefits increased by 105 percent. The replacement rate for a median wage earner retiring at age 65 rose from 29.6 percent in 1969 to 44.7 percent in 1977. With a dependent spouse age 62, the replacement rate reached 62 percent.[4] Those who also received pensions found that the social security benefit often was the greater of the two. Moreover, social security benefits were permanently tied to the Consumer Price Index in 1975, a feature that was virtually absent in private pension plans.

Part of the increase in social security benefits was intentional, for example, the *ad hoc* increases before 1975 and the indexing of benefits. However, part of the increase was the unintended byproduct of a faulty benefit computation formula, enacted in 1972 and effective starting in 1975. This—the famous decoupling problem—drove future benefits upward faster than expected, and overcompensated for inflation.[5] The problem was—one hopes—corrected by the 1977 amendments.

Understandably, the pension community became nervous. As early as 1970, Robert J. Meyers sounded the warning that "expansionists" in the Social Security Administration sought to change social security from a floor of protection to a virtually complete replacement of preretirement income.[6] Pension planners indeed had cause to worry. If social security benefits continued to increase, they might crowd out the need for pensions. It is not surprising, therefore, that, by the mid-1970's, the labor movement no longer placed priority on social security benefit increases, leaving some room for pension improvements at the bargaining table.[7]

The 1977 amendments to the Social Security Act have ended the rise of benefits as measured by the replacement rate. As a result, social security is now less likely to crowd out pensions, and the latter will retain their importance as income maintenance for future retired workers. □

New Spanish legislation marks turning point in labor relations

BENJAMIN MARTIN

Organized labor in Spain partakes of the highly political character that distinguishes trade unionism in the Latin countries of Western Europe. But the Spanish political climate in recent years has taken on inordinate dimensions; the initial years of the democratic transition have been a time of acute rivalries as contending political forces fiercely compete for power and electoral influence. The unexpectedly large support received by the Socialists in the June 1977 parliamentary election prompted the center-right government of Prime Minister Adolfo Suarez to enter a tacit collaboration with the Communists, for the purpose of containing the Socialist resurgence, a development that inevitably influenced the formulation of government labor policies.

The Suarez government has regarded the unions almost exclusively in political terms because the two leading labor confederations are controlled by Socialists and Communists. In its estimation, therefore, other than for purposes of political manipulation, there was little incentive to promote basic reforms in labor legislation. There was, on the other hand, good reason to maintain the unions in limbo, in a weakened state to aid the ruling Union of the Democratic Center Party (UCD) in its effort to establish a third major labor center that would serve as the government's labor adjunct.

Nor were the actions of the Socialist and Communist Parties conducive to effective trade union development. Engrossed in a crucial contest for political advantage, their respective trade union arms were constrained to concern themselves at least as much, if not more with political mobilization and tactics than with essential trade union tasks. In such an environment, institutional needs and the credibility of the unions necessarily suffered.

Turning point

The outcome of the March 1, 1979, parliamentary election marked a perceptible change. The election results reflected a decisive turnback of a Socialist challenge to the continued incumbency of the Suarez government, and a strengthened parliamentary standing for the victorious UCD. Accrued political strength and the reasonable assurance of remaining in power until 1983 persuaded the government in recent months to abandon its alliance with the Communist Party (PCE). Moreover, since the Socialist Workers Party (PSOE) no longer represents a threat to tenure, to a greater extent than before, the country's principal parties have found it mutually beneficial to establish working compromises on pending legislation. An example is the new Statute of the Workers, passed by the Congress of Deputies on December 20, 1979.

Most likely it was employer influence that was instrumental in the government's decision to embark on a new approach both to industrial relations and to the Communists. The Spanish Confederation of Employer Organizations (CEOE), which serves as the principal spokesman for employer interests, is endeavoring to reduce the highly interventionist government role inherited from the Franco regime, and to carve out for itself a larger role in the setting of economic and labor policies.

In July 1979, before the inauguration of parliamentary discussions on the proposed labor statute, the CEOE and the General Union of Workers (UGT) (which is allied with the Socialist Party) entered into a pact that set forth their joint support for a number of proposed provisions of the labor code. This unprecedented development set the stage for the subsequent unveiling of the new policy.

The pact marked a major departure not only for the future configuration of labor-management relations but also as a portent of the change in attitude toward the Communists. The principal thrust of PCE strategy is designed to increase the party's own acceptability. The Workers Commissions, as a consequence, have insisted that the setting of national economic and labor policies should be taken up in formal discussions among government, employers, unions, and the political parties. The UGT argued that such matters require labor-management consultations to lend them a more functional character, and to establish the practice of high-level labor-management consultations. When the CEOE sided

---

Benjamin Martin is a labor specialist, formerly at the Department of State.

with UGT on the issue, the Workers Commissions withdrew from the talks.

The UGT also emerged the gainer in a dispute with the Workers Commissions over the roles to be accorded respectively to the unions and the factory works councils. The Workers Commissions have consistently sought to confer wide ranging powers on the works councils, including the right to negotiate on wage and other economic issues, in order to exploit both its appreciable superiority in experienced cadres and UGT's deficiency in this area. The UGT, on the other hand, has argued in favor of a larger role for the unions at the plant level and has proposed a delineation of functions similar to what prevails in most West European countries: that works councils be empowered to represent workers with respect to most nonwage matters, while unions bargain for wages, hours, and related issues. Both the pact with CEOE and the provisions of the new statute favor the UGT approach.

Concern about Communism

An underlying factor in this rapprochement has been mounting concern in employer and center-right political circles that the tacit alliance between the Suarez government and the Communists, if it were to continue, might eventually lead to Communist labor hegemony, especially since the government's effort to create its own trade union arm has ended in total failure. In the moderates' and rightists' view, therefore, a new policy was required, one that would reduce the PCE's disproportionate influence in the country's political life. As a result, the CEOE-UGT pact, the adoption of a labor statute that incorporated the UGT-CEOE proposals, and the government's change of attitude toward the Communists all heralded an important shift in labor policy and in the country's political alignments.

Such a shift required the government to improve relations with the PSOE and UGT. The latter, who regard the PCE and Workers Commissions more as rivals than as appropriate collaborators, view the government's current attempt to politically isolate its erstwhile allies as excessive and potentially counter-productive, but are, nevertheless, disposed to enter working agreements with the Suarez government on specific issues. The Communist Party and the leadership of the Workers Commissions understandably have denounced the new statute as retrograde and prejudicial to the workers' interests. While the new law may be somewhat partial to employer interests it is, nonetheless, constructive in a number of important aspects. It holds up fairly well when compared with similar legislation in other West European countries. Further, despite the acute political controversy accompanying the passage of the Statute of the Workers, the logjam preventing the establishment of a coherent post-Franco labor relations structure has been breached at long last.

Viewed in broader context, the democratic evolution process now seems to have attained sufficient stability to render possible the inauguration of a similar evolution in labor-management relations as well. The establishment of "rules of the game" signifies that a gradual institutionalization of the collective bargaining process and role definitions of the protagonists can now proceed along structured lines. For the unions that have fallen on hard times, a strengthening of their role in the new collective bargaining system and in the formulation of national economic policies holds the promise of eventually providing them with an institutional capacity. This has thus far eluded them, as has the gradual emergence of a specific trade union voice in the country's economic and social life. Such an evolution, should it come to pass, could serve to liberate the unions from their presently excessive dependence on the political parties. Throughout the initial years of Spain's democratic transition the trade union-party nexus has tended to function as a largely unilateral transmission belt rather than as a mutually beneficial channel between allied, but not always congruent, interests. □

Family Budgets

Rise in autumn 1979 family budgets marked by transportation and taxes

Reflecting large increases in transportation and medical costs, and personal income taxes, the three hypothetical budgets for an urban family of four in autumn 1979 averaged $12,585 a year at the lower level, $20,517 at the intermediate level, and $30,317 at the higher level.[1] (See table 1.) From autumn 1978 to autumn 1979, the lower budget rose 9.0 percent, the intermediate, 10.2 percent, and the higher, 10.6 percent. (See table 2.)

Consumption costs. Consumption costs rose by approximately 9 percent in the lower budget and 10 percent in the intermediate and higher budgets between autumn 1978 and autumn 1979. The largest increases in consumption costs for all three budgets were in transportation and medical care, and in homeowner costs for the intermediate and higher budgets (See table 3.)

The large increases in food costs in the previous year, approximately 12 percent for the lower level and 13 percent for the intermediate and higher level budgets, were replaced by lesser increases of 9.4 percent for the lower and intermediate budgets and 9.5 percent for the higher budget.

Tax changes. The budgets include Federal, State, and local tax payments. Changes in Federal Laws provided for increased deduction for personal exemptions, higher standard deductions for the assumed family type in the budgets, and a decrease in tax rates. These deductions were offset by higher tax rates corresponding to higher incomes. The net result was that total personal income taxes increased approximately 10 percent at the lower level and 11 percent at the intermediate and higher levels. This contrasts to the 1977–78 income tax changes where taxes at the lower level rose 30 percent, and at the intermediate and higher level, 17 and 15 percent.

Table 1. Annual budgets for a 4-person urban family, at 3 levels of living, autumn 1979

Component	Level		
	Lower	Intermediate	High
Total budget	$12,585	$20,517	$30,317
Total family consumption	10,234	15,353	21,069
Food	3,911	5,044	6,360
Housing	2,409	4,594	6,971
Transportation	1,004	1,851	2,411
Clothing	866	1,235	1,804
Personal care	323	433	613
Medical care	1,171	1,176	1,227
Other family consumption	550	1,021	1,684
Other items	538	877	1,478
Social security and disability	781	1,256	1,413
Personal income taxes	1,032	3,031	6,357

Total budget	9.0	10.2	10.6

[1] Includes only rental housing in the lower budget.

[2] On the assumption that the home was purchased 6 years ago, these costs reflect changes in purchase prices and mortgage interest rates from 1972 to 1973; and changes in property taxes, insurance, fuel and utilities, and repairs and maintenance from 1978 to 1979.

Housing and utilities. Housing consists of rental units only in the lower budget, and increased by 7.9 percent between autumn 1978 and autumn 1979. In the intermediate and higher budgets, housing includes both rentals and homeownership, and increased by 9.9 percent, largely because of increases in mortgage interest during 1972–73, and substantial increases in fuel and utility costs. Increases in housing costs had a greater impact on the intermediate and higher budgets than on the lower budgets, not only because of large rises in homeowner costs but also because housing accounts for a larger share of the consumption dollar at those levels.

The social security tax rate rose from 6.05 in 1978 to 6.13 percent in 1979, and the maximum income on which it is deducted increased from $17,700 to $22,900. The family budgets represent the costs of three hypo-

[1] The family consists of an employed husband, age 38, a wife not employed outside the home, an 8-year-old girl, and a 13-year-old boy.

[2] As defined in 1960–61. For a detailed description of these and previous geographical boundaries, see the 1967 edition of *Standard Metropolitan Statistical Areas*, prepared by the Office of Management and Budget.

[3] Places with population of 2,500 to 50,000.

[4] Housing includes shelter, housefurnishings, and household operations.

[5] Renter costs include average cotract rent plus the cost of required amounts of heating fuel, gas, electricity, water, specified equipment, and insurance on household contents.

[6] Homeowner costs include interest and principal payments plus taxes; insurance on house and contents; water, refuse disposal, heating fuel, gas, electricity, and specified equipment; and home repairs and maintenance costs.

[7] The average costs of automobile owners and nonowners in the intermediate budget were weighted by the following proportions of families: Boston, New York, Chicago, and Philadelphia, 80 percent for owners, 20 percent for nonowners; Baltimore, Cleveland, Detroit, Los Angeles, Pittsburgh, San Francisco, St. Louis, and Washington, D.C., with populations of 1.4 million or more in 1960, 95 percent for automobile owners and 5 percent for nonowners; all other areas, 100 percent for automobile owners.

[8] In total medical care, the average costs of medical insurance were weighted by the following proportions: 30 percent for families paying full cost of insurance, 26 percent for families paying half cost; 44 percent for families covered by noncontributory insurance plans (paid by employer).

[9] Other family consumption includes average costs for reading, recreation, tobacco products, alcoholic beverages, education, and miscellaneous expenditures.

*Some areas previously shown are no longer available.

thetical lists of goods and services that were specified in the mid–1960's to portray three relative standards of living described as lower, intermediate, and higher. These budgets are for a precisely defined urban family of four: a 38 year-old husband employed full time, his non-working wife, a boy of 13, and a girl of 8. The family has, for each budget level, average inventories of clothing, housefurnishings, major durables, and other articles. The budgets pertain only to an urban family with the specified characteristics; no budgets are available for rural families. The budgets are not intended to represent a minimum level of adequate income or a subsistence level of living, nor do they indicate how families do or should spend their money.

Users should note that the procedures used in updating the budgets to 1979 differ from procedures used in 1978. As a result of the revision of the CPI program in January 1978, individual area price changes from autumn 1978 to autumn 1979 were available for only 25 of the44 family budget areas. The urban U.S. average includes estimates for these areas, however, using price data for the appropriate region and population size classes which are available from the CPI. Nonmetropolitan areas, which have always been shown as a separate class, have been similarly updated.

Complete data on the three family budgets can be obtained from the Bureau of Labor Statistics or any of its regional offices. ☐

Research Summaries

The workweek in 1979: fewer but longer workdays

JANICE NEIPERT HEDGES

The 4-day 40-hour workweek is the best known, but perhaps not the most significant, illustration of a trend toward fewer but longer workdays for full-time workers. Schedules that exceed the 40-hour standard are increasingly compressed into 5 days in order to provide a 2-day weekend.

The number of wage and salary workers who usually work 5.5 or 6 days a week declined by more than one-half million in the 6 years ended May 1979.[1] (See table 1.) This drop occurred despite a gain of about 1 million in the group of workers who are most likely to work more than 5 days, namely, those who work 41 hours or more per week. The explanation lies in the growing practice of squeezing the workweek into 5 days or less even if this requires workdays of 9 or 10 hours or even more.

The compression of weekly hours into fewer days is evident below and above the 40-hour standard workweek. Among employees who usually work 35 to 39 hours, the proportion working 4.5 days or less increased from 5 to 7 percent from 1973 to 1979. Among those who usually work 41 to 48 hours, three-fifths were on 5-day schedules in 1979—up from less than one-half 6 years earlier. The trend away from 5.5 and 6-day weeks was evident even for those who work 49 hours or more a week. (See table 2.)

The push toward fewer but longer days is seen most clearly in the data for workweeks of a specific number of hours, rather than those which are expressed in intervals of hours, as the latter may mask movement within the interval (for example, relatively fewer workers at or near the upper margin). Thus, among employees who reported working 44 hours, the proportion working more than a 5-day schedule declined from one-half to one-third from 1973 to 1979. Among those working 48 hours a week, the proportion working more than 5 days declined from one-fourth to one-fifth.

The modest reductions in the weekly hours of wage and salary employees in this 6-year period (reflected in a decline from 42.5 to 42.3 in the average usual hours of full-time employees) fell far short of organized labor's

often stated objective of a 4-day, 32-hour week. They did, however, facilitate the compression. A 5-day schedule is more feasible with a 45-hour week, for example, than with a 50-hour week. Nonetheless, in 1979, the number of workers who regularly worked 10 hours a day for 5 days was several times the number who worked 10 hours daily for 4 days (2.3 million versus .5 million.)

In the early 1970's, the 4-day, 40-hour workweek had been heralded as the successor to the standard 5-day week. At the close of the decade, however, 64 percent of all wage and salary workers, or 1 percentage point more than in 1973, were on 5-day, 40-hour schedules. Growth in the number of 4-day employees since 1977 had no more than kept pace with the overall growth in wage and salary employment. Work schedules which gave employees some choice in the timing of their work (for example, flexitime) seemed to be taking hold but had not resulted in any significant change in the number of workdays in the week.[2]

Compressed 4-day workweeks had come to be considered largely as special schedules. They were being used, for example, to provide larger police forces during high crime periods and to increase the utilization of

[2] Not available.

NOTE: Because of rounding, sums of individual items may not equal totals.

capital equipment by scheduling more work outside the traditional daytime shifts. In continuous operations, rotating, 12-hour shifts that combined workweeks of 4 days with 3-day workweeks were being introduced to provide employees with more days off (and more free weekends) than under traditional scheduling.[3] Some viewed the 4-day workweek primarily as an energy conservation device in the event of a national emergency.[4]

The greater prevalence of workweeks of any given number of days in some industries than in others indicates special requirements in those industries as well as legal restrictions and custom. Five-day schedules were very widespread in Federal public administration in 1979 where employees were covered by requirements of the Federal Pay Act for premium pay after 8 hours work a day.[5] (See table 3.) Schedules of fewer than 5 days occurred most often in local government, largely because of the use of such schedules for police and firefighters. Full-time workweeks of 5.5 and 6 days were more common in trade than elsewhere, in part, because stores generally operate more days than offices or factories. In the service-producing sector as a whole, both longer and shorter workweeks were a little more prevalent than in the goods-producing group.

Wide differences also are observed by occupation. Clerical occupations had by far the highest proportion of 5-day workers, while workweeks of 5.5 and 6 days were most common for sales employees and managers and administrators. Service workers, 6 percent of whom were on schedules of 4.5 days or less, were more likely than other groups to work full time in fewer than 5 days. Among transportation equipment operators (a group that includes truck drivers), both the proportion working 4 days and the proportion working 6 days were higher than the overall average.

Overall, the proportion of full-time wage and salary workers who usually work 5 days or less, rose by 3 percentage points, to almost 84 percent, in the 6 years ended May 1979. ☐

———*FOOTNOTES*———

[1] Findings in this report are based on information collected once a year since 1973 through a May supplement to the monthly Current Population Survey, which is conducted for the Bureau of Labor Statistics by the Bureau of the Census. The information is provided by a question, "How many days a week does . . . . usually work at this job?," cross-classified with questions on the monthly schedules. The data refer to the number of days per week that are usually worked by nonfarm wage and salary employees who work full time (35 hours or more) on their sole or primary job.

[2] Flexitime in its simplest form has no impact on the number of days worked; employees can vary the hour at which they begin and end work, but are required to put in a full day every day. However, under more advanced forms of flexitime, workers can work longer days occasionally to shorten their workweek by a half day, or even more.

[5] The Federal Employees Flexible & Compressed Work Schedules Act of 1978 (Public Law 95–390) has temporarily suspended these provisions for agencies or work units participating in approved experiments with work schedules.

Most workers find jobs through word of mouth

MARY CORCORAN, LINDA DATCHER,
AND GREG J. DUNCAN

A majority of workers heard about their current jobs through friends and relatives, according to a recent nationally representative sample of adult workers, and more than one-third of all workers had help in getting their jobs. Black men were as likely as white men to have heard about or obtained their current jobs informally. Informal channels were used more among young workers, less educated workers, and blue-collar workers.

These data are from the 11th wave of the Panel Study of Income Dynamics, an ongoing, longitudinal study of more than 5,000 American families which was begun in 1968.[1] The sample for this study is restricted to male household heads, female household heads, and wives, all of whom were under age 45 in 1978 and worked at least 250 hours in 1977. There were 3,759 observations; 1,499 white men, 667 black men, 988 white women, and 605 black women. When weighted, these data represent the population of young working adults living in their own households. All heads of households responded for themselves; for married couples, husbands reported for their wives.

Three distinct aspects of informal job search were investigated: "search at the extensive margin," "search at the intensive margin," and "influence patterns." Search at the extensive margin involves workers obtaining wage offers from additional employers; search at the intensive margin involves obtaining additional information about job offers already in hand.[2] Responses to the first question, "How did you first hear about a job with your

present employer—was it through a friend, a relative, a want ad, an employment agency, or what?" provide some information about search at the extensive margin. Responses to the second question, "Before you got your first job with your present employer, did you know anyone who worked there?" provide a dichotomous measure of information at the intensive margin. Personal contacts who are already working for a potential employer may provide jobseekers with useful information about working conditions, fringe benefits, and advancement opportunities. Responses to the third set of questions, "Do you think there was anyone who may have helped you get the job?" and "How did they help?" provide measures of influence, that is, whether the workers received any help at all from personal contacts in getting their current jobs.

How workers hear about their jobs

Friends, relatives, and personal contacts were a major source of information and help to workers seeking jobs. About half of all workers heard about their current job through a friend or relative and about half knew someone who worked for their current employer before they began work. Reports of influence, while less common, were still numerous. About 40 percent of the men and one-third of the women reported that someone helped them get their current job.

In contrast to some previous findings,[3] we found that black men were more likely than white men to have heard about a job from a friend. In addition, they were more likely to have known someone who worked there and to be helped by someone in getting the job. But looking at the kind of help received, white men were somewhat more likely to report having received direct help than were black men.

Women were considerably less likely than men to have used informal information and influence channels in obtaining their current jobs. Recall, however, that husbands reported on their wives' use of such channels. Such a difference would be expected if husbands systematically underestimated the extent to which their wives had access to friendship networks to learn about and get jobs. When women's use of informal information and influence channels was compared by marital status, we found that white female heads of households and white wives were equally likely to have used such channels. Black female heads, on the other hand, consistently reported more use of such channels than did black wives. This information could be accurate rather than the result of husbands' misreporting because the pressure to get high wage jobs is stronger for female heads of households. However, black female heads reported considerably less use of such channels than did black men and slightly less than did white men.

Users of contacts

Table 1 examines use of informal information and influence networks by education and occupation. Construction of the first two variables, "Heard about current job from a friend or relative," and "Knew someone on current job," is self-explanatory. The third, "Received help on current job" is formed from affirmative responses to the first question regarding influence.

Regardless of race-sex group, workers with college

[2] Fewer than 10 observations.

and advanced degrees and professional workers were considerably less likely than the average worker to report having used informal information and influence channels in obtaining their current jobs. While more than half of all white men reported having heard about their current job from a friend, only 32 percent of white male professionals, only 39 percent of white men with B.A. degrees and only 23 percent of white men with advanced degrees reported that they heard about their current job from a friend. Forty percent of all white men reported that someone helped them get their present job, but only one-third of the white men with professional jobs, college degrees, or advanced degrees reported such help. White men in blue-collar occupations were more likely than other white men to hear about their job from a friend, to know someone on the job, and to be helped by someone. Perhaps, informal information and influence networks substitute for the more formal credentials used by well-educated and professional workers.

The three information and influence measures were regressed on schooling, job tenure, and on age when the job was taken. For white men, education and the age when they took the job were negatively associated with all three information and influence measures and significantly so in all but one instance. That is, the younger and less educated a white man was when he obtained a job, the more likely it was that he heard about that job from friends or relatives, that he knew someone who worked there, that someone helped him get the job, or that he both knew someone and received help getting the job.

Part of the negative associations with workers' education and age may be an occupational effect. That is, well-educated and older workers may be more likely to seek work in occupations which emphasize formal credentials and past experience or training. Results when occupation is controlled suggest that this may be true for schooling, but not for the age when the job was taken. When occupation is controlled, the magnitude of the negative association between schooling and the information and influence measures dropped sharply for white men. But controls for occupation had no effect on the negative association between the ages when people took their current job and influence and information measures.

For the other groups, the amount of schooling and the age when workers took their jobs were not consistently associated with the measures of informal information and influence. For black men, schooling was negatively and significantly associated with knowing someone and having received help, but these associations dropped sharply and became insignificant once occupation was controlled. □

Conflicts among work, leisure, and family roles

GRAHAM L. STAINES AND PAMELA O'CONNOR

Workers in the 1977 Quality of Employment Survey were asked, "How much do your job and your free time activities interfere with each other?"[1] A third of the 1,515 workers reported that conflict between work and free time activities occurred "a lot" or "somewhat."

When asked "In what ways do they interfere with each other?" these workers most frequently mentioned excessive amounts of work which prevented them from spending enough time in other activities. The second most common complaint involved work schedules that interfered with leisure. "Other" time conflicts ranked third and reports that work makes the worker too tired or too irritated to engage in leisure activities were fourth.

Demographic subgroups of workers reported different types of conflict between work and leisure. Men, who on average work more hours than women, were significantly more likely than women to report excessive amounts of work. Older workers (45 years and over) were significantly less likely than younger workers to report excessive amounts of work, scheduling conflicts, or spillover from work of fatigue and irritation. Married workers were more likely than unmarried workers to report excessive amounts of work, but were less likely to report scheduling conflicts. Parental responsibility was positively and significantly associated with reports of

excessive amounts of work, but not with reports of the other types of interference. Workers with a high school diploma cited spillover of fatigue and irritation more frequently than did workers in other educational categories, but education was not related to the other types of interference. Workers in managerial and administrative occupations were the group most likely to complain of excessive work, whereas service workers were the group most inclined to mention scheduling conflicts.

Factors associated with conflict

Conflict between work and leisure clearly appears related to the demographic characteristics of the worker and to various dimensions of work, leisure, and family roles.[2] Table 1 summarizes the findings for the degree of conflict associated with demographic factors. The "mean" in the table is the average value of response to the question: "How much do your job and your free time activities interfere with each other?" Degrees of interference were scored from 1 to 4 points, with "not at all" equaling 1 point and "a lot" equaling 4 points.

Working men reported significantly more conflict between work and leisure than did working women, as did younger workers (under age 45), compared with older workers. The degree of interference was not related to marital status but was positively and significantly related to level of parental responsibilities: parents of children under age 6 were more likely to report conflict, followed by parents of school-age children, and then workers with no children at home. Moreover, workers with a college degree or above reported significantly more conflict than did those with less education. Among the major occupational groups, workers in managerial and administrative occupations registered the highest level of conflict.

Table 1. Reported conflict between work and leisure, by selected demographic characteristics

Characteristic	Mean[1]
Sex:	
Men	[2]2.26
Women	[2]2.10
Age:	
Under 30 years	[2]2.29
30-44 years	[2]2.29
45 years and older	[2]2.02
Marital status:	
Married	[3]2.23
Not married	[3]2.13
Parental status:	
No children	[2]2.13
Youngest child 6-17 years	[2]2.22
Youngest child under 6 years	[2]2.34

Crafts	[2]2.15
Operatives	[2]2.39
Service	[2]2.07

[1] The mean is the average value of response to the question: "How much do your job and your free time activities interfere with each other?" Degrees of interference were scored from 1 to 4 points, with "not at all" equaling 1 and "a lot" equaling 4. Levels of significance indicate the presence of significant differences among subgroup means (based on analysis of variance).

[2] Significant at .01.

[3] Not significant.

A number of work-related items were significantly related to work-leisure conflict. (See table 2.) As expected, amount of time spent on the job was positively and significantly related to interference. Another significant factor was shift assignment: workers on afternoon or night shifts reported the highest levels of interference; those on day shifts reported the lowest level; and those on rotating shifts or other irregular patterns registered scores in between.

The significance that workers assign to their work role was assessed by asking the following two questions: "How often do you think about your job when you're busy doing something else? Often, sometimes, rarely, never" (role perseveration); and "How much do you agree or disagree that the most important things that happen to you involve your job? Strongly agree, agree, disagree, strongly disagree" (role importance). Role perseveration was significantly and positively related to interference, but role importance was not. Interference produced a significantly negative relationship with satisfaction with work.[3]

Several leisure-related items also are related significantly to reported conflict between work and leisure. (See table 3.) Although an index of frequency of leisure activities[4] was not related to degree of conflict, an index of variety of leisure activities was positively and significantly related to interference. In other words, it is not so much the total amount of leisure activity as the number of different types of leisure activities that appears to predict interference. When specific leisure activities were considered separately, two contrasting patterns were evidenced. Frequency of participation in those activities that required leaving the house and going to a scheduled event (for example, a concert, play, movie, or party) was significantly associated with high levels of work-leisure conflict. Participation in informal activities that take place at or near home (for example, working on hobbies at home or working around the house) tended to be negatively related to conflict, especially among those who at least sometimes engage in the activity; in the case of watching television, there was a significantly negative relationship (that is, more viewing was associated with lower conflict). Thus, individuals can reduce high levels of work-leisure conflict by opting for informal and easily organized leisure activities, especially television viewing. Furthermore, time spent on leisure during a workday was significantly negatively related to work-leisure interference, although leisure time on a day off was not.[5] In addition, the significance of leisure (role perseveration, role importance) was positively and significantly associated with work-leisure conflict, whereas satisfaction with leisure produced a significantly negative association.[6]

Certain dimensions of family roles were also related to degree of work-leisure conflict. Interference increased significantly for one measure of the significance of family life (role importance), but not with the other (role perseveration), and interference produced a significantly negative relationship to satisfaction with both family life and marriage.[7]

In sum, reports of work-leisure conflict tend to be positively associated with involvement in all major roles of life (work, leisure, family), regardless of whether involvement is measured in behavioral (variety of activities, time allocated) or attitudinal (significance assigned to role) terms. Exception: conflict is negatively related to time spent on leisure during a workday. In addition, such conflict is consistently associated with low satisfaction with each of the major roles of life.

Inferred conflict

An alternative measure of conflict between work and leisure involves bivariate relationships between the amount of time spent at work and the amount of time spent on leisure activities. Generally, time spent in these activities should be negatively related (that is, the more time spent in one role, the less time available for other roles). This "inferred conflict" approach assumes that the stronger the negative bivariate relationship (or the weaker the positive relationship), the greater the level of conflict.

Actually, reported conflict and inferred conflict differ in a number of methodological respects. Reported conflict represents a subjective approach to measurement, inferred conflict a more objective approach; reported conflict incorporates all types of conflict between work and leisure, inferred conflict taps only the conflict concerning amount of time; reported conflict is measured at the level of the individual worker, inferred conflict is measured at an aggregate level; and, while reported conflict is measured for only two pairs of roles (work and leisure, work and family), inferred conflict may be assessed for any and all role pairings.

Data on reported and inferred conflict are best compared in terms of demographic differences regarding time. Reported conflict between work and leisure (and, likewise, between work and family life) was greater for men than for women on the issue of excessive time spent at work. Similarly, for work and leisure and also for work and two family roles (childcare and home chores), inferred conflict (as indicated by the strength of negative relationships among amounts of time spent in various roles) was greater for men than for women.[8] This difference can be explained by the fact that men work longer hours than women and the amount of time they spend at work generates more conflict between work and other roles.

Table 2. Reported conflict between work and leisure, by selected work-related items

Item	Mean [1]
Time on the job: [2]	
6.9 hours or less	[3]2.05
7.0–7.9 hours	[3]2.13
8.0 hours	[3]2.12
8.1–9.9 hours	[3]2.25
10 hours or more	[3]2.47

Somewhat	[3]2.30
Very	[3]2.02

[1] See table 1, footnote 1.

[2] Time spent working on a workday was assessed using the question "During the average week, how many hours do you work, not counting the time you take off for meals?" For each worker, the number of hours worked per week was then divided by the number of days worked to yield an average number of hours worked per day.

[3] Significant at .01.

[4] Day or regular shift starts between 4 a.m. and 12 noon, afternoon shift starts between 12 noon and 8 p.m., and night shift starts between 8 p.m. and 4 a.m.

[5] Not significant.

By the same token, because women spend more time than men in family roles, inferred conflict between leisure and family roles and also among family roles should be greater for women than for men. For the most part, it was. (See table 4.) The bivariate association between leisure time and time spent in childcare was significantly positive for men both on workdays and on days off, but was significantly negative for women on workdays and not significant on days off. For men, the relationship between the time spent on leisure and home chores was significantly positive for workdays and not significant for days off; yet for women it was not significant for workdays and significantly negative for days off. On days off, time spent in two family roles, childcare and home chores, was significantly positively related among men, but not significantly related among women. On workdays, however, a contrary pattern appeared: time allocated to these two family roles was positively and significantly related, but more so for women than for men.

To summarize, when workers have to devote substantial time to a demanding social role (for example, work, childcare, or home chores), conflicts arise concerning the magnitude of time allotments. In the case of work, the issue of excessive time applies more to men than to women, based on data from both the reported and inferred approaches to measuring conflict. In the case of family roles, the pattern is reversed; with one exception, the data on inferred conflict indicate that women experience greater time conflict among leisure and family roles than do men.

These data on inferred conflict among leisure and family roles call for additional interpretation. The concept of partial overlap of activities offers the best explanation of positive relationships among time spent in these roles: when an appreciable number of activities qualify as belonging equally to two different roles, a positive association may emerge between the amounts of time allocated to the two roles.

[1] The mean is the average value of response to these questions: "On the average, on days when you're working, about how much time do you spend on your free time activities? . . . And about how much time on days when you're not working?" "On average, on days when you're working, about how much time do you spend (taking care of or) doing things with your children? . . . And how much time on days when you're not working?" "On the average, on days when you're working, about how much time do you spend on home chores — things like cooking, cleaning, repairs, shopping, yardwork and keeping track of money and bills? . . . And how much time on days when you're not working?"

[2] Includes only parents with children under age 18.

[3] Significant at .01.

[4] Significant at .05.

[5] Not significant.

The notion of partial overlap also applies to the differences in inferred role conflicts among men and women; in particular, to the fact that the bivariate associations among time spent in leisure and family roles tend to be positive for men and negative for women. Among men, there would appear to be some overlap of leisure and childcare activities, likewise between leisure activities and home chores and, by implication, between childcare and home chores. Generally, leisure is thought of as more enjoyable than either childcare responsibilities or home chores. Thus, the postulated overlap of activities among men raises the possibility that the leisure of men (but not women) may include childcare responsibilities and home chores. Because working men reported significantly greater satisfaction with their leisure and with their family life than did working women, it is likely that the childcare activities and home chores of working men are sufficiently enjoyable to be considered leisure. In the case of childcare, for example, many men presumably allow their wives to assume most of the demanding and least enjoyable responsibilities, so that the time they spend with their children is consequently viewed as recreational. There is also the further possibility that fathers, at most, are expected to help with the children, whereas mothers typically have the much more demanding assignment of taking responsibility for them.[9]

The one finding based on inferred conflict that remains to be explained concerns the relationship between the two family roles (childcare and home chores) on workdays. As noted, women registered a stronger positive association between time allocated to these two roles on workdays than did men. The inference that women experience less conflict between childcare and home chores on workdays should be resisted, because the associations for both sexes are appreciably positive. Far more plausible is the contention that in their typical rush for time on workdays, mothers who work outside the home perform these two activities simultaneously, while fathers engage in only one activity at a time.[10] Thus, because mothers perform their childcare responsibilities and home chores in parallel fashion during the limited amount of time they have available on workdays, their time allocations emerge as more strongly and positively associated than do those of fathers.

WHEN THE ISSUE is amount of time, data based on measures of both reported conflict and inferred conflict indicate that interference between work and leisure and between work and family roles is greater among men than women. Yet, additional data on inferred conflict suggest that conflicts between leisure and family roles and between the two family roles studied (childcare and home chores) tend to be greater for women than men. □

FOOTNOTES

[1] Details of the survey's sample, measures, and response distributions appear in Robert P. Quinn and Graham L. Staines, *The 1977 Quality of Employment Survey* (Ann Arbor, Mich., Survey Research Center, 1979). For a general discussion of the survey's results, see Graham L. Staines and Robert P. Quinn, "American workers evaluate the quality of their jobs," *Monthly Labor Review*, January 1979, pp. 3–12.

[2] For a detailed discussion of work-family conflict, see Joseph H. Pleck, Graham L. Staines, and Linda Lang, "Conflicts between work and family life," *Monthly Labor Review*, March 1980, pp. 29–32.

[3] Satisfaction was determined in terms of the question: "All in all, how satisfied would you say you are with your job? Very satisfied, somewhat satisfied, not too satisfied, or not at all satisfied."

[4] Respondents were asked about the frequency of their participation in specific leisure activities: "How often do you . . . (1) watch television, (2) read newspapers, magazines, or books, (3) visit with family, friends, or neighbors, either at each other's homes or by telephone, (4) play in athletic games or do other active things like go bike riding or swimming, (5) work on hobbies at home, (6) work around the house or yard for pleasure, (7) eat out at restaurants, (8) go to museums, concerts, plays, or lectures, (9) go to the movies, (10) go to parties, nightclubs, or dancing places, (11) go to church or synagogue?" The responses ranged from "nearly every day" to "never." From these measures, we derived an index of frequency of leisure activities which is the average of the scores for all leisure categories for which the worker reported frequency of participation, with each category scored from zero ("never") to seven ("nearly every day") and an index of variety of leisure activities which is the number of different types of leisure in which the worker engages at least several times a year (the worker received one point for each type of leisure for which his or her response was something other than "never" or "once a year or less").

[5] Amount of time spent on leisure was measured by asking, "On the average, on days when you're working, about how much time do you spend on your free time activities? . . . And about how much time on days when you're not working?"

[6] The questions used to assess the significance of leisure activities (role perseveration and role importance) and the measure of satisfaction with leisure activities were the same as those for significance of work, except that the phrase "your job" was replaced with "your free time activities."

[7] The questions used to measure significance of family life correspond closely to those used for work and leisure. For role importance, the phrase "your husband/wife and your children" replaced the phrases "your job" and "your free time activities." In the case of role perseveration, this substitution of phrases is repeated and, in addition, the response categories are slightly modified to take into account a more negatively skewed response distribution: "How often do you think about your husband/wife and your children when you're busy doing other things? Always, often, sometimes, rarely." For similar reasons, the questions measuring satisfaction with family life and with marriage likewise required modifications: "All in all, how satisfied would you say you are with your family life?" and "All in all, how satisfied would you say you are with your marriage? Extremely satisfied, very satisfied, somewhat satisfied, not too satisfied."

[8] The measures of time spent in these two family roles resemble the earlier measures on time spent on leisure: "On average, on days when you're working, about how much time do you spend (taking care of or) doing things with your children? . . . And how much time on days when you're not working?" "On the average, on days when you're working, about how much time do you spend on home chores—things like cooking, cleaning, repairs, shopping, yardwork, and keeping track of money and bills? . . . And how much time on days when you're not working?"

[9] Similarly, an intensive investigation of 14 families in which both husband and wife worked suggested that although husbands share certain childcare duties with their wives, the responsibility for seeing that such tasks get done ultimately falls on the wives in most cases. See Laura Lein, *Work and Family Life* (Cambridge, Mass., Center for the Study of Public Policy, 1974), pp. 45–46.

[10] Lein comments specifically on this sex difference in the simultaneity of activities: "Unlike mothers who are trying to do other chores while watching their children, fathers' hours of child care are more often devoted to child care exclusively." (See *Work and Family Life*, p. 109.)

Foreign Labor Developments

American wood products workers study European job safety systems

MATT WITT

A delegation from the International Woodworkers of America and the American Labor Education Center has completed a month-long tour to study occupational safety and health practices in Sweden, West Germany, and Austria.[1] Group members, including local union safety committee representatives, union safety staff, and government officials from Washington State and British Columbia, visited 20 sawmills, papermills, hardboard plants, and logging operations in the three countries. They met with local union and management officials at each site and spoke to officials of unions, companies, and government agencies.

The Swedish method

The Swedish system is the most comprehensive. Its centerpiece is a national Work Environment Fund, created in 1972 and financed by a 0.1 percent payroll tax on all employers. Its board includes equal representatives of labor and management, plus a chairperson who is a retired union president. The fund primarily finances research and training. Its annual budget for work environment research is approximately $22 million, with topics including control of noise, toxic substances and stress, ergonomics, and health effects of various work schedules.

Proposals are presented to the fund by researchers in universities and private firms, then reviewed by committees of employers and union representatives in each industry. Under a special current project, the fund is spending more than $1 million to train union staff members to both evaluate research proposals and generate more of their own.

In the wood products industry, one environmental research group has been working in 15 sawmills, a similar group has concentrated on factories, such as furniture and prefab housing plants, and another has worked in forestry under an additional $1 million fund grant. These groups include engineers, doctors, professors, psychologists, and representatives of the unions, employers, and equipment manufacturers. Their achievements are explained to the unions' regional safety representatives, at the fund's expense, who pass the results on to local union stewards.

The International Woodworkers of America delegation observed many operations which, aided by research findings, are now meeting Sweden's standard for average daily noise exposure of 85 decibels. (The U.S. standard is 90 decibels.) In sawmills visited by the delegation, airborne dust levels were reduced below 1 milligram per cubic meter through use of enclosures for saws and local ventilation. Pentachlorophenols, widely used as wood preservatives in the United States, have been removed from Swedish mills because of concern about their effect on workers' reproductive systems. Chain saw-related hand and wrist injuries in the logging industry were reduced by 90 percent between 1967 and 1976, chiefly due to innovative designs for hand guards. Following the introduction of chain brakes, foot and leg injuries were reduced by more than 50 percent in one year.

Since 1974, the fund has paid for the training of about 250,000 local union safety stewards and supervisors (from a work force of 4.1 million). Individual employers pay the lost-time wages (nearly $30 million per year) for those in training.

The 40-hour basic courses cover such topics as workplace planning, noise, ventilation, toxic substances, illumination, ergonomics, and psychosocial factors such as job satisfaction. Training is conducted by the unions in "study circles" rather than in the formal classroom style used in the United States. Trained study circle leaders, who generally are workers rather than safety technicians, guide the discussions. Written materials and film strips explain basic principles, which are then applied by the students during special workplace inspections. A study circle graduate goes back to work with lists of conditions which must be corrected.

Committees created

Under a combination of national laws and contracts, there must be enough elected safety stewards at every workplace with 5 employees or more to cover each work area on each shift. Each workplace with 50 em-

ployees or more must have a labor-management safety committee with more than half of its members elected by the union. In smaller workplaces, a committee must be created if the workers feel it necessary; otherwise, a representative from the appropriate union region performs the committee functions. The committees (or the regional representatives) have the right to:

- Veto any plans for new machines, materials, or work processes for health and safety reasons.
- Decide how to spend the company health and safety budget which is usually negotiated through local bargaining.
- Approve the selection and direct the work of the company doctor, nurse, safety engineer, or industrial hygienist.
- Review all corporate medical records, monitoring results, and other information on hazards.
- Shut down dangerous operations until hazards can be corrected.
- Decide how much time (all company paid) they need to do their safety committee work.

The role of the Swedish government is primarily to set health and safety standards and to make inspections when safety committees are unable to resolve problems or do not have the necessary technical expertise. The National Board of Occupational Safety and Health, the Swedish counterpart to the U.S. Occupational Safety and Health Administration (OSHA), has one inspector for every 400 workplaces (compared to OSHA's one for more than 3,000). Swedish inspectors can levy fines and have health and safety changes made, at the employer's expense, if the company has failed to comply with a previous directive.

In West Germany and Austria, the delegation observed a health and safety system based on the "works council"—committees which represent workers on all types of grievances. These committees do not have any independent powers like those in Sweden, and are not necessarily an arm of the local union. German and Austrian workers cannot be required to join their union (and in many industries a majority does not), yet the works council is elected by *all* employees at each operation. Training for works council members is conducted in classroom format, dealing mainly with economic issues rather than health and safety.

In both West Germany and Austria, most responsibility for standard setting, inspections, training, and workers' compensation is borne by insurance institutes in each industry. The institutes are run jointly by management and labor and financed by premiums based on industry and company safety records. Those in the wood products industry do not conduct or sponsor any significant amount of health and safety research, leaving that to employers and equipment manufacturers.

After returning home, the delegation persuaded its international union convention to authorize an experimental project in which the union will attempt to set up Swedish-style research committees. The union is conducting a health and safety survey of its members who use chain saws, and will then ask logging companies, saw manufacturers, and government officials to help improve saw design. The union is also asking the Consumer Product Safety Commission to consider the views of professional chain saw users before approving new safety standards. Union officials say they hope to gradually adapt other aspects of the Swedish system, such as company-paid research funds and paid training for safety committee members, through future regional and local contract negotiations. ☐

Educational leave in Canada: a look at individual programs

ISAIAH A. LITVAK AND CHRISTOPHER J. MAULE

Canadian interest in educational leave has increased in recent years. This can be partially attributed to Canada's membership in the Organization for Economic Cooperation and Development (OECD) and the International Labor Organization (ILO), which have sponsored conferences and studies on the subject of educational leave.[1] One of the results of this interest and participation was the establishment of a Federal Government "Industrial Inquiry Commission" in 1978.[2]

The identification and evaluation of the issues involved in educational leave are still in a fairly primitive state, and to shed some light on the subject, particularly from the standpoint of policy implications, we examined the leave policies and practices of 13 employers,[3] including Canadian and foreign-owned firms. The sample is biased toward organizations with some known commitment to education but still reflects differences in size, nationality of ownership, industry representation, technology, and organizational mission.

Five of the organizations are in the public sector and employ from 500 to 80,000 unionized workers. The remaining eight organizations are manufacturing and ser-

vice firms in the private sector, employing from 65 to 20,000 persons. Five of the companies are essentially nonunionized.

Case method used

We used the case method to collect data in 1978, structuring our interviews along the lines of a recent OECD study and modified to reflect Canadian circumstances.[4]

We found it difficult to obtain information of a consistent nature within and between the organizations. Only one of the private organizations had stated educational leave policies; the policies of the rest were ad hoc or negotiable. There was an absence of good documentation on the extent, nature, and costs of the educational leave and little effort to evaluate its impact.

Interviews were conducted with managers, employees, union representatives, educational officials, consultants, government officials, and professionals in an attempt to become familiar with the details of the policies and practices of each organization.

We defined educational leave to be leave taken in excess of 3 months, which is spent during regular working hours for full-time studies, directly or indirectly related to employment.[5]

All five public sector organizations have educational leave programs, four of which are formally structured. In all instances, the form of financing ranges from full to partial to none. While at first glance the educational leave programs appear to be well established, they are infrequently used except by the Federal Government. Leave recipients are primarily managers or technocrats, or those being groomed for these positions. With one exception, the recipients attend institutions of higher learning. Information on leave provisions is readily available and communicated within 4 of the 5 public sector organizations.

The situation is dramatically different in the private sector. Four of the companies provide no opportunity for educational leave, while it is only negotiable in the remaining four. The few participants to date have been largely managerial and salaried employees. Information about leave opportunities is quite selective, and tends to be communicated to the more ambitious management employees. In the case of the small firms, none of which is foreign-owned, educational leave is not available.

Employers' perspective

We will discuss public and private sector employers separately because they tend to have different attitudes.

Public sector employers tended to favor the introduction of educational leave because of the size of their organizations, and because employees were not likely to leave the organization, although they might transfer from one department to another. Secondly, because public sector organizations are not evaluated in terms of profit performance, it is easier to administer a policy which is difficult to evaluate and which would be questioned much more closely in a profit-oriented organization. Thirdly, public sector organizations feel that educational leave provides some skills they could not otherwise acquire. Educational leave is here viewed as a technique for manpower planning.

In contrast to these supportive factors, the system of educational leave has been abused by using it to sideline personnel or to provide a stepping stone to early retirement. Also, in a time of fiscal restraint, educational leave is a policy that is an early victim of cost cutting, and a no-growth or slow-growth public sector employment situation means there is less pressure to acquire personnel, however well qualified.

Private sector employers are in general lukewarm to the idea of educational leave, but large companies could be persuaded of its merits if it was a way of holding on to their best employees, or providing skills which could not be otherwise purchased. Small and medium-sized firms, however, fear the individual could easily be hired away.

Private sector organizations argue against educational leave on the grounds that it would not enhance their profitability, that they can buy the skills which they require, and also cite problems of replacing employees, who are away for lengthy periods, as well as problems of re-entry into the organization at an appropriate level. Those firms which are willing to consider educational leave tend only to do so if it is leave without pay. Accountancy is an example of a profession whose members require neither pay while on educational leave nor job security if leave is taken, because they become an even more marketable item.

Employees' viewpoint

The employee position on educational leave was articulated by union locals, union headquarters, and organizations such as the Canadian Labor Congress. In general, the union locals had less interest in promoting educational leave than did the other union components, because of a perceived difference of interest. The federation's position was more attuned to and knowledgable of the position put forward by the ILO, as well as the educational leave situation in some European countries. Union headquarters were also familiar with the general issues that have been debated, but their interest was largely ideological, and they argued for leave for union educational purposes. Lip service might be paid to leave for social purposes, but unions were more concerned with promoting understanding of their union among the existing members. In industries such as printing, technological change is already resulting in the alteration of union membership, and educational leave could be seen by a union as a further disturbing factor.

At the local level, which is where the cases concentrated, educational leave received little consideration for a number of reasons. In a period of prosperity, educational leave is viewed by union locals as one of a number of fringe benefits that are negotiable. In times of recession, educational leave was of very low priority or was not even considered. The concern of locals tends to be concentrated on provisions for training and retraining in the face of recession and technological change. Educational leave is not considered an issue if the union member does not have a job, so locals concentrate on immediate employment, hourly rates, and training so that the member remains employed. In this regard, both the firm and the local are in agreement in stressing the need for training facilities and programs.

The professions (doctors, nurses, accountants) appear as a special group because of the type of service that they sell, and because they involve an element of self-regulation. While the professions tend to restrict entry through certification requirements, which often involve extensive education in colleges and universities, their concern with certifying existing practitioners falls off once the individual has qualified for the profession. All three professions included in the case studies made statements about the type of study which an individual should undertake to ensure career development, and maintain the necessary professional qualifications. However, little attempt is made to enforce provisions for continuing education.

The case studies revealed that there were different attitudes toward educational leave by the three professions. The accountants received leave without pay; the doctors who were attached to a university received a sabbatical leave with partial pay, and those employed by the hospital could negotiate a similar arrangement; the nurses seldom received leave with pay, but did have access to external funding sources. The association of nurses took the view that it was the individual's responsibility to remain qualified. In sum, the attitude of professionals to educational leave would tend to vary among professions according to the role of the association, the contractual conditions of work, and the form in which payment is received.

Government's position

As a policymaker, the Federal Government has an extensive manpower policy program which is oriented toward training the currently unemployed, or those threatened with unemployment. This policy tends to be focused on job-specific training to expand employment and as such coincides with the attitudes of private firms and union locals.

A lesser concern to date with educational leave has probably been because of the extensive government financing of colleges and universities, which has resulted in a higher proportion of the work force in Canada attending such institutions than has been the case in European countries. As a pace setter, governments have introduced affirmative action, both in terms of their own and other organizations' hiring procedures. However, to date, affirmative action has been enforced through moral suasion and guidelines, rather than through enforceable rules. □

Significant Decisions In Labor Cases

To the victor, what spoils?

In a recent 6 to 3 decision, the Supreme Court curbed the patronage practices of local governments by ruling that the First and Fourteenth Amendments prohibit the dismissal of patronage appointees solely on the basis of their political beliefs, unless the hiring authority can prove party affiliation a necessary condition for the effective execution of the appointee's office. (*Branti v. Finkel.*[1]) This decision further expanded the principles set forth in *Elrod v. Burns*[2] by divorcing questions of party affiliation from the confidentiality or policymaking status of a public office.

Two assistant public defenders for Rockland County, N.Y., appointed under the 1972–76 Republican administration, sought to prevent their dismissal by the newly selected Democratic public defender, Peter Branti. Asserting that the announced dismissals stemmed solely from the attorneys' Republican affiliation rather than unsatisfactory job performance, a Federal district court, upheld by the Second Circuit, enjoined Branti from firing the pair.

Branti provided the Court with an interesting opportunity to further delineate and clarify the constitutional status of political patronage. In *Elrod,* the Court held unconstitutional a requirement that certain patronage employees change party allegiance as a condition of continued employment. The *Branti* case took the dilemma a step further. Have an employee's rights been violated if he has not been coerced into switching parties, but has been discharged simply because he lacks the sponsorship of the party in power? Still another issue was raised: even if party sponsorship is an unconstitutional condition of employment for *Elrod*-type employees (whose duties were primarily clerical and janitorial), is party affiliation an acceptable condition for a position that may involve policy decisions such as assistant public defender?

In a majority decision written by Justice John Paul Stevens, the Court ruled that the attempted Branti dismissals, even though they did not involve explicit coercion nevertheless would infringe on the employees' First Amendment rights. Expanding on *Elrod,* Stevens wrote, "If the First Amendment protects a public employee from discharge base on what he has said, it must also protect him from discharge based on what he believes . . . his beliefs cannot be the sole basis for depriving him of continued public employment." Stevens dismissed the assertion that an employee's rights are violated only if he is forced to change his party affiliation, arguing "such an interpretation would surely emasculate the principles set forth in *Elrod* . . . it would not eliminate the coercion of belief that necessarily flows from the knowledge that one must have a sponsor in the dominant party in order to retain one's job." Stevens concluded, " . . . there is no requirement that dismissed employees prove that they, or other employees have been coerced into changing either actually or ostensibly, their party allegiance" for them to gain reinstatement; it suffices to prove that such dismissals derived solely from party affiliation.

Less straightforward was the Court's reasoning regarding the constitutionality of requirements of party sponsorship for positions deemed policymaking or confidential. The Court conceded that party affiliation may be an acceptable, even necessary condition for some types of government employment, but countered that it is not relevant to every policymaking or confidential post. "In sum, the ultimate inquiry is not whether the label 'policymaker' or 'confidential' fits a particular position; rather the question is whether a hiring authority can demonstrate that party affiliation is an appropriate requirement for the effective performance of the public office involved." Moving from the broader issue to the circumstances of the case, the Court reasoned the position of public defender cannot properly be conditioned on party affiliation, because the policymaking functions of the position relate to the problems of individual clients rather than partisan political interests. In upholding the Second Circuit, the majority concluded any effort to link office tenure to party affiliation would undermine the integrity of the assistant public defender.
